The occupational hazard is often obscure, but is clearly developed when careful records are kept of all disease among a large number of workmen in many occupations, as was done by "The Local Sick Benefit Society of Leipzig and Vicinity" for the period 1887-1904 These records showed that the number of days lost per year on account of sickness varied according to occupation from four days for clerks and salesmen to 12 15 for polishers and metal grinders, 12 56 days for iron and steel workers and 14 43 days for refiners in sugar factories

2 *Conditions for Which the Public is Responsible* —The conditions for which the public is primarily responsible are community conditions In times now passed health authorities confined themselves to operating quarantines and the abatement of nuisances, but now under the broadening influence of a clearer knowledge of the causes of disease, they are extending their activities beyond what was originally considered the province of the government At first they went beyond the streets and public places and fixed regulations for proper housing, pure water, pure food, sanitary workshops As working and living conditions have become more complex, the duties of the public have developed until now its regulatory power is extending into the home and shop, and the highest courts of the land are upholding this power, as is seen in decisions affirming the right of the state to limit hours of work and to compel the payment of wages to women which will be sufficient to maintain an adequate and healthful standard of living

3 *Conditions for Which the Employees are Responsible* —With all the conditions for which the public and employers are responsible eliminated, there still remains a large residue for which the employees are

* Read before the Section on Preventive Medicine and Public Health at the Sixty Sixth Annual Session of the American Medical Association San Francisco, June 1915

[1] Duke, Emma Infant Mortality U S Children's Bureau, p 45

[2] American Labor Legislation Review, 1910, i, No 1, p 125

responsible. In spite of the realization of employers of a larger degree of responsibility for the health of the workers, and in spite of the ever-broadening sphere of public activities to protect the health of all citizens, there remains the individual responsibility for the home environment. It must be stated, however, that the responsibility for their environment does not rest altogether on the workers. No one is able to choose every part of one's environment, and this is especially true of many workers who have little or no choice, but must accept what is offered in the way of employment, and must also accept the home environment for which they can pay with the wages earned. This will continue to be true, especially in the unskilled group, so long as the supply of laborers is greater than the demand and the competition for employment makes it possible for the employer to fix the terms of employment.

The great burden of maintaining proper hygienic standards in the home, after all, rests on the wage earners, who are least able to bear it and who are so often ignorant of their importance. Physicians know, from experience, of the inability of individual wage earners to meet this responsibility, but they are apt to conclude that volunteer welfare workers, relief societies, and charity organizations are providing for the cases which come to their knowledge.

It is necessary, therefore, to point out that recent investigations show that about one half of the native-born families and two thirds of the foreign-born families in the United States had incomes of less than $750 a year. Seventeen per cent. of all native-born and one third of all foreign-born families had incomes of less than $500 a year.[3] These investigations included incomes from all sources and included earnings of wives and children and payments from boarders and lodgers. The inadequacy of these incomes may be measured when it is stated that the consensus of conclusions taken from a number of careful studies of expenditures of workingmen's families show that an average family cannot live for less than $800 to $900 per annum. (The average family is defined as composed of man, wife, and three children under 14 years.) In small cities and towns where rents are lower, the amount required is smaller. But even in these towns a minimum of $700 to $800 may be fixed with the assurance that the amount required is more rather than less.

The adequacy of this standard may be judged by the manner of expenditure, as shown by budgets studied in families living in New England and other Eastern cities, whose incomes averaged about $750 a year, the family being of the average size.

TABLE SHOWING DISTRIBUTION OF FAMILY BUDGET

	Per Cent. of Income	Amount
Food	47	$360
Rent	17	126
Clothing	16	123
Fuel and light	5	41
Health	2	17
Sundries	13	98
Total	100	$765

With an income of $750 a year and an expenditure of $650 a year for the bare necessities of living, the narrow margin is all too apparent. When the numerous necessary sundry expenses are deducted from the margin of $100, there is little left to provide a surplus to meet the expenses of an emergency. No reasonable thrift can save from this small margin a sum sufficient to pay for a death, an additional birth, or unusual sickness.

The question may well be raised as to whether an income of $750 is sufficient for the average family. As to more than half of all the workingmen's families in the United States whose income is less than $750 a year there can be no doubt as to their inability to maintain healthful conditions in the home.

The conclusion is apparent, therefore, that the largest share of the responsibility for the wage-earner's health rests on the workers who cannot carry the load. Society expects these to carry the greatest part of the burden of sickness, when under the best conditions they can barely meet expenses and furthermore they have the least experience in disease prevention. This is expected of them after they are handicapped by an environment which our social organization has for centuries decreed for those who are unskilled or untrained for some trade.

TREND TOWARD COLLECTIVE ACTION AND INSURANCE METHODS

With the responsibility for the wage-earners' health so definitely fixed on the employer, the employee and the public, and with this responsibility so intimately related that the duties often overlap, cooperative action is apparently the best remedy. Collective action is the only method which will enable each group immediately to meet the problem of relief of sickness without greatly increasing the amount now expended for this purpose. If this collective action is further extended into the field of disease prevention, the present cost can be greatly reduced. This is, in fact, the essential principle of sickness insurance.

Insurance is a method by which a group of persons, each in danger of some loss, the incidence of which cannot be foreseen, can distribute the cost of such loss, where it occurs to any of them, over the whole group and lighten the burden of its most serious economic effects. The results are the strongest incentive to lessen the cost by diminishing the frequency of losses. In sickness insurance the employer, the employee and the public pay the premiums for insurance against the loss to which each group is liable in case of sickness of employees. In this way the loss is distributed and a strong incentive created in each group to reduce the cost by preventing sickness. This division of the cost would greatly reduce the amount now spent by employees for sickness, and distributes the payment over such a long period of time that the poorest paid wage earner can meet the expense without materially lowering his present standard of living. Furthermore, it would meet this expense in a businesslike way and leaves no "taint of charity."

While relief of sickness must be the primary object of sickness insurance, prevention of sickness will be the greatest result. There can be little doubt as to this when the results of insurance in other fields are studied. It is only necessary to mention fire insurance and the great effort to prevent fires by building regulations, fire inspections and the like, marine insurance and efforts to prevent losses at sea, and accident insurance and the "Safety First" movement.

The experience with sickness insurance in foreign countries has been such that practically every European country has some form of sickness insurance law, and in those countries with comprehensive laws, the results in stimulating efforts to prevent sickness have been very encouraging It is also a significant fact that no country which has enacted laws on this subject has repealed them, on the contrary, many have extended and strengthened them

---

[3] Reports of the U. S. Immigration Commission 1911, xix, 125.

In the United States no state has enacted a law on the subject, but there are several million persons insured against sickness in labor unions, establishment funds, fraternal orders, or commercial companies It is therefore no novelty in this country, but a method which is growing popular, as is shown by the increasing demand

A PRACTICAL PLAN FOR SICKNESS INSURANCE

To meet the requirements for the relief and prevention of sickness in the United States, a sickness insurance law could be enacted by Congress to apply to all industries in all the states, or by the state legislature to apply within the state

An examination of the most successful European governmental systems of sickness insurance and of the principles and methods practiced by mutual benefit societies, trade unions, and industrial establishments in this country suggests that a sickness insurance system, whether state or local, should include the following provisions

1 *Insured Persons*—All persons engaged in gainful occupations and earning a specified annual income ($1,000 or less) should be entitled to the benefits provided under the law

All persons earning more than the specified annual income should be allowed to qualify for the same benefits or greater benefits according to annual income

2 *Funds*—A tentative ratio of contributions has been suggested as follows

Employees	50 per cent
Employers	40 per cent
Government	10 per cent.

Provision should be made for persons earning more than the specified income whereby they could pay a larger proportion of the contributions and receive larger benefits

3 *Benefits*—The following benefits should be provided

Cash Benefits Weekly cash payments to begin after the first week of disability due to sickness, nonindustrial accident, or to child bearing by the beneficiary, for a period not to exceed twenty-six weeks in one fiscal year

Death Benefits Cash payment to legal heirs for death due to sickness or nonindustrial accident

Medical Benefits To include adequate medical and surgical care, beginning with the first day of disability, whether due to sickness, nonindustrial accident, or to child bearing by the beneficiary or the wife of the beneficiary, and limited to a period of twenty-six weeks in one fiscal year unless the time is extended by the commission

4 *Cost*—Preliminary estimates indicate that the total contributions would not need to exceed 50 cents per week per insured person, that is, employee 25 cents, employer 20 cents and government 5 cents, for a minimum of benefits of $7 per week for disability beginning after the first week, $200 for death, and adequate medical and surgical care

5 *Administration*—All matters of promulgation of rules and regulations and appeals should be vested in a commission created for this purpose

Subject to appeal to the commission, all executive authority should be vested in a director appointed for this purpose

Subject to appeal to the director, all medical benefits should be under the supervision of the medical director who should be closely related to the health department

All matters of local administration should be vested in local boards of directors which should be federated according to districts, in order to lower the costs and increase the efficiency of local administration All local and federated bodies should be subject to supervision by the central authorities, and also subject to the rules and regulations promulgated by the commission

The commission and all local and federated boards should be composed of persons representing the contributors to the funds The number representing employees and employers should be in the same ratio as their respective contributions

Provision should be made for free choice of any physician registered on the local panel, and all persons licensed under the laws to practice medicine should be allowed to register on the panels But the number selecting any one physician should be limited

Relation to the Medical Profession—Without adequate medical benefits, both clinical and preventive, the whole plan will prove a failure

These benefits should provide adequate medical and surgical relief, including specialist and dental services, medicines and appliances in home, hospital, or office, as the case may require, for all disability as provided under the law or regulation

To provide these benefits there should be a corps of all-time medical officers and nurses, and local panels of physicians, specialists, dentists and druggists to provide such relief as may be authorized by the annual contract

Corps of All-Time Medical and Health Officers—The officers of the medical corps should be carefully selected, and after a probationary period of satisfactory service, given a life appointment subject to dismissal for inefficiency or immoral conduct

In the federal plan the medical officers should be detailed from the present United States Public Health Service

In the state plan a medical corps should be created along the same plans as the present commissioned corps of the Public Health Service and the state health department reorganized on such plans as would provide an efficient supervision of the medical benefits

The duties of the medical corps under federal or state plan should be to have charge of all hospital and dispensary relief, to examine all insured persons claiming to be disabled, and issue certificates in accordance with the regulations promulgated by the commission, to advise the administrative authorities and all contributors to the funds as to the best measures for the relief and prevention of sickness, to advise with the physicians attending sick members as to measures which will shorten the periods of disability, and to perform such other duties as may be fixed by regulations The corps of nurses should be selected and appointed in the same manner as the medical corps, and should aid the medical corps in all of the duties required of it

The further duty of visiting and nursing disabled members in their homes should be imposed on the nurse corps under the direction of the attending physician or visiting board of the funds, as the case may be, but always under the supervision and approval of the medical corps

Panels of Physicians, Specialists, Dentists and Druggists—In every local or federated jurisdiction, panels of physicians, specialists, dentists, and druggists should be contracted with to furnish adequate services to all insured persons who prefer to be treated in their home or in private office

These contracts should, by preference, be made through the medical societies and all the administrative details left to the societies, but strict provision should be made that any person, licensed under the state laws as competent to perform the services specified, must be allowed to register on the specified panels without regard to the particular school said person may have graduated from

Each insured person should have the privilege of making his own choice of physician from among those registered on the panel for his district This choice should be allowed once each year, or oftener if some good reason is furnished The number choosing the same physician should be limited to such extent as will insure adequate service on the part of the physician

Payment for services should be made on a per capita basis and each physician should receive the same annual amount per patient whether the patient is sick or well At the end of each month or quarter the physician should receive pay in accordance with the number of insured who had selected him

The same methods of capitation payment and selection should be provided for dentists and druggists

This method of payment and selection should prove to be for the best interests of all concerned Those rendering services or selling medicines and appliances should receive the same capitation fee and there would be no incentive to render excessive services or furnish excessive supplies of medicines or appliances in order to increase their income On the other hand, the fact that the patient has the right to change his choice would be incentive sufficient to make those chosen do their best to please.

There will be a further inducement to render efficient service to all patients in the fact that an officer of the medical corps will have to see every disabled member as often as may be necessary to keep informed as to his disability in order to issue the certificate required This double medical examination would not only increase the efficiency of the treatment, but would prevent malingering as it is not apt to be successful under the double examination and observation

Hospitals and Dispensaries—As rapidly as possible local boards of directors should be federated according to the most favorable districts so as to build, buy or contract with hospitals and dispensaries for the care of its disabled members These should be placed in charge of the medical corps and contracts be made for such special services as may be required Any patient should be admitted to hospital or dispensary treatment on the approval of a regular medical officer, but the amount of the capitation paid to any doctor or druggist for any person so admitted should not be reduced because of such admission

Visiting Boards—To further insure that every beneficiary received just treatment and none be allowed benefits to which he is not entitled, provision should be made for the organization of visiting boards composed of insured persons whose duty should be to keep in touch with each disabled member until he has recovered These visiting boards should also keep in touch with the medical officers and visiting nurses on duty in their district.

THE POSSIBILITIES OF SUCH A SYSTEM

Of course, it is borne in mind that a system of sickness insurance such as has been outlined should be evolved through federal or state legislation, or both, and that starting in a limited field it could be gradually extended and perfected But the beginnings of a cooperative governmental system should be made as soon as possible with the object in view that each one of the 30,000 000 workers in the United States should eventually receive adequate medical and surgical care

With adequate financial relief when unemployed on account of sickness, he would be able to take advantage of the treatment before it was too late

There would be funds with which to build or buy hospitals in every federated district These hospitals would be in the reach of all and form part of the benefits to which all would be entitled

The treatment in the homes would have to be of the best, or the patient would be sent to the hospital Minor ailments, many of which now go uncared for because of the expense, would receive prompt attention in office or dispensary Physicians would no doubt institute thorough, periodic examinations of the physical conditions of their clientele, knowing that such examinations would often save their patients from many serious troubles

Visiting nurses and visiting boards would find in homes many conditions which needed correction to save future trouble The all-time medical officers would enter the homes of all sick members and with the trained eye of the sanitarian would find many causes of disease which need correction

Health departments would not have to spend time in lobbying to obtain proper laws and appropriations Instead, business men, on finding that they were paying for much disease that could be prevented, would see to it that the health authorities were efficient and effective in the work of disease prevention

PHYSICIANS ARE NOW HANDICAPPED

At present medical practice in the United States is operating on a most uneconomical and unsocial basis The man on the average income of industrial workers cannot afford to pay the charges for the average sickness expectancy Among these the physicians are practicing against heavy odds

A large number of low-paid wage earners and members of their families constitute the "charity practice" of physicians, and many of them are found in the free hospitals and clinics where physicians give their services free, and many more, too proud to ask for charity treatment, either get no treatment at all, treatment too long delayed, or treatment of dubious value from quacks, "patent medicine" men, druggists, and ignorant midwives

In medical centers large free hospitals are maintained for certain patients called hospital patients, while other patients must go without treatment and many of the hospital patients do not apply for admission because they cannot afford to stop work

Outside of medical centers there are many large areas which have few or no physicians, because the people are too poor to employ them

For the most part, throughout the United States hospital accommodations are far from adequate

The results of this lack of treatment or improper treatment of the poorly paid workers is that many die every year who could be saved, untold numbers become permanently disabled and unable to work their wives become invalids from no care or improper care during confinement, and thousands of their children die within the first year of life from lack of intelligent care, or become blind, or are otherwise handicapped

SICKNESS INSURANCE A HEALTH MEASURE

A governmental system of sickness insurance similar to those in successful operation in Europe will enable the physician to receive pay for his practice and hospital work among low-paid wage-earners, and will allow the patient to receive prompt and proper treatment without forcing him to become a "ward of charity" It will strengthen the economic independence of the worker and at the same time greatly increase and stabilize the income of the physician as well as enable the medical profession to carry on a more effective preventive work

The waste from disability and death due to preventable disease is so tremendous that estimates mean nothing to the average mind The suffering and sorrow due to these causes should be sufficient argument for a sickness insurance law which will place adequate medical relief within the reach of all and provide for preventive measures on a broad and comprehensive plan in which there will be a financial incentive for employers, employees, physicians, and the community to prevent sickness Such a law would prove to be the greatest public-health measure ever enacted

DISCUSSION

ON PAPERS OF DRS MCCURDY, SNOW AND WARREN

Mr Frederick L Hoffman, Newark, N J Any plan of national or state sickness insurance is and ever will be primarily a medical question It matters very little as to how the end is achieved to those who are or will be the beneficiaries of the plan It matters very little whether it is done by insurance, or whether it is done through the taxing power of the state I believe that those who are responsible for the English national insurance scheme, if they could have their way and go over the ground again, would not call it an insurance scheme at all, but a national public health service If we are really sound in our democracy, that the interest of every individual is a matter of government concern, as regards health and longevity, strength and efficiency, then I believe it goes without saying that sooner or later we shall adopt a rational and effective method to carry such an idea as that of Dr Warren and others into effect At the present time an enormous amount of ill health exists in the community in that latent incipient form, when there is the greatest reluctance to seek advice, although there is then the greatest possibility of real prevention and of genuine cure That reluctance is, of course, due largely, if not entirely, to economic reasons—to the unwillingness or the inability on the part of a large number of wage earners (and with these we are chiefly concerned) and their dependents, to incur the initial expense It has been said—and I believe it is true—that the majority of our wage workers have not a single week's wages ahead Now, if that is true, and if that amounts to $10 or $15, you can see how narrow the margin is between economic dependence and economic independence If the state, or if insurance companies and societies, can induce the wage earner, however, to set aside a very small portion of his wages, so small that he would not feel it at all, that amount stretched over the course of his life and accumulated at compound interest will, broadly speaking, prove fully sufficient to provide for him and his dependents adequate medical treatment, adequate surgical treatment, adequate medical inspection, and other means for the prevention of illness as well as its cure Unfortunately, whenever you approach a wage earner with so remote a contingency as sickness (for it is remote, broadly speaking, in the life of the large majority of that proportion of our wage earners who are mostly under 30 years of age), they are, as a rule, unwilling to make that present, though small, pecuniary sacrifice, and in the European countries, at least, compulsion has been the only alternative to a really universal and thoroughly effective system of what we call social insurance, but what really amounts to a system of state medicine They call it insurance, but nothing is insurance in the true sense that rests on compulsion, on the one hand, and on a state or an employer's contribution, on the other It is simply a modified form of taxation, and if we are going to have anything of that sort in this country, we must face it from that point of view I should like to leave that thought with you, for it is of the utmost importance that there should be no confusion of terms

Dr George M Kober, Washington, D C The importance of the subject of industrial sanitation must be apparent when it is remembered that probably more than one third of the population in this country constitute our working classes Health is the chief asset of the working man, and no greater calamity can befall him than when, by reason of sickness or accident, his earning capacity ceases It means in many instances the utter financial ruin of the family and is doubtless one of the most potent causes of poverty and distress An appeal has been made by Dr McCurdy for an enlightened and humane interest in this important and much neglected subject There has been need for it ever since the mechanical industries sprang into existence, and it is much to our shame that we have been so tardy to realize the imperative need for active preventive work in connection with industrial diseases and accidents I certainly hope that the papers that have been presented will make a deep and lasting impression, and enroll into the ranks of workers in industrial sanitation a large number of able and faithful and intelligent men and women for the prevention of needless suffering and distress I merely want to point out that of the 143,000 deaths from tuberculosis which were recorded in the census of 1913, probably more than one half belong to the industrial workers, and it has been estimated that fully one half of all these lives could have been saved by the enactment and enforcement of laws for the prevention and removal of dust and fumes, which constitute the foes of industrial life That is only one of the many instances that can be cited in favor of active preventive measures Time does not permit me to speak of many other factors connected with this great problem, such as industrial poisons, fatigue from overwork and long hours, the question of temperature and atmospheric conditions One of the most important conditions is reasonable hours of work How can we expect men to work day after day and month after month and year after year without wearing themselves out, as long as the hours amount to ten, eleven and twelve as we very frequently find in our steel plants, where they are exposed not only to extreme, hard physical work, but also to excessive heat and other avoidable conditions detrimental to health and life?

Dr R W Corwin, Pueblo, Colo Our work must extend further than examination of the man in the mill His home surroundings should be considered If possible he should be freed from anxiety, insanitary and unhygienic conditions

Our attention should be called also to the matter of education Not only should the employee be instructed, but those above him in authority The doctor learns new prophylactic facts every day All others may do the same.

We hear much regarding the use and abuse of tobacco and liquor No person in authority can ask one under him not to do what he himself indulges in One cannot expect of his assistants more than he is willing to do himself

Dr G H Richardson, San Francisco For the past two or three years, as a member of the Commonwealth Club of this city, I have been studying the various phases of social insurance, and have become very much interested in this subject, particularly as it relates to our profession I want to bring out one point that was brought to my mind by Dr McCurdy's paper on the physical examination of employees I examine for the Civil Service Commission of San Francisco and of course make a large number of rejections, but I have kept no record of these rejections All over the United States these examinations are being made, and it would be of great service to compile these rejections The statistics would, I am sure, be of some service to this section The same thing I know exists in the recruiting depots of the army, the navy and of the marine service We have no easy way of knowing the character of the defects giving rise to their rejections, the proportion of men rejected, or most important of all, the ultimate result of these defects on the earning capacity of the individual It would seem that if they were collected by this section in some proper manner, it would be of value to us in this work The dark war cloud that now rests over Europe will practically socialize that continent It is going to make poverty such as the world has never seen, and in consequence the various countries will have to tax themselves, probably by some form of compulsory insurance, to care for their great dependent populations We must expect that this transition in economic life will affect conditions in the United States, and we as medical men should study and prepare ourselves for the wonderful change it will make on our profession as a means of livelihood and also on our relations to the sick and injured of our community

Dr G H Taubles, San Francisco With reference to the paper of Dr Snow, one of the strong things brought up but not elaborated was the instance of enormous numbers of girls living under most distressing conditions, and, on the other hand, the statistics of men infected with venereal diseases, most of them unmarried I think that this is the age of the awakening of the civic conscience, and this condition is one that requires readjustment The mass of people cannot be deprived of their biologic heritage by the isolation of large numbers under unsuited conditions, causing many of those women to pass through their lives without ever having completed their functions of motherhood, by ruining so many of these men so that they never will have completed their functions of fatherhood This thing in time must have a serious effect on the entire population The hopeful thing is that such a section as that of preventive medicine has sprung into existence, and it is from the social aspect that preventive medicine will have its strongest effect That readjustment must take place and the reestablishment of human beings as biologic functioning organisms must take place, and that is social This is going to be emphasized, particularly at this time, in view of the enormous destruction of life occurring in Europe, and the problem will be presented to us in the United States from the point of view of immigration We will have many hundreds of thousands of people to take care of directly, and hundreds of thousands to take care of indirectly The United States has always sent a great portion of its natural products to other continents This will be more than ever the case in the next decades

Dr. W C Rucker, Washington, D C Dr McCurdy spoke of the question of overloading the human machine Years ago the reports of the Marine Hospital Service were filled with references to aneurysm among sailors, which was then very common Nowadays aneurysms are almost never found among sailors This is coincident with the substitution of gasoline and steam power on ships in place of man power for the purpose of hoisting sails moving boats, warping in vessels and everything of the kind I believe this has reduced aneurysm among sailors, and that what applies to this one craft applies to all others

With regard to the examination of applicants for positions, on two occasions I have been entrusted with the employment of large numbers of men, and, like everyone who has done this sort of work, I have observed the very close relation between the physical and mental development of men, but there is a type of men physically sound and apparently fairly sound mentally who nevertheless have a mental strabismus In the employment of men, the exclusion of such applicants is most important They are invariably trouble makers, a danger to fellow workers and cost a great deal more than they are worth The simple test of the imagination is one of the best tests for the exclusion of these men, as they invariably have a disordered imagination If you present to them a sudden emergency requiring the exercise of the imagination you will be surprised at the queer and eccentric answers you will get, and whenever you find men with these queer imaginations it is not wise to employ them For the common laborer, the man who is supposed to bring a little brain and a great deal of muscle to his job, a blot makes a very good imagination test Simply take your pen and put some ink on a piece of paper, fold it and unfold it again, and, pointing to the blot, say to the man, "What does it make you think of?" That sounds like an idiotic test, but it is really a sensible test for these men They will display emotional characteristics under this stimulus to their imagination Here is a blot that looks to a normal eye like a cloud, and the man is apt to say, "Oh that looks like a brainstorm Take it away"—something like that You will find it a good test

I have told these things to bring out the importance of the test of the mental condition of workmen, of which nothing was said in the papers The importance of such a test is illustrated by the case of a man, employed as a boatman running a small gasoline craft, who suddenly began to hit things, bumping into the wharf and injuring his boat His friends and his employers noticed it, but paid little attention to it Within a year he had general paresis

A good many railroad accidents have been due to the fact that the men were in the stages of mental deterioration I think in our routine physical examination of employees we should pay great attention to their mental condition

Dr. Leo Munter, San Francisco The proposition of sickness and accident insurance I believe to be dangerous and bad The matter of industrial insurance as we have it in San Francisco has proved to be a bad proposition At the time when the insurance act first went into effect there were compacts made between physicians of San Francisco and various parts of the state with the insurance companies, whereby the physician was to furnish his services at a minimum fee The argument was made that industrial insurance was to protect a class of men who were making small wages, who were not earning sufficient to protect themselves in case of accident, and for that reason the medical men were asked to make their fees as low as possible The argument was also made by the insurance companies and by the industrial accident commission that as we ordinarily charged low fees to these men, we should not charge the insurance companies larger fees for the services rendered As a result, the association of insurance companies adopted a schedule, which was all the way from 50 to 60 per cent lower than the regular fees that had been charged for medical services A great many physicians were requested to sign this schedule and pledge themselves to work for these fees A great many physicians of San Francisco, to my own personal knowledge, did sign this schedule and agreed to do the work for this minimum fee At a meeting of the State Medical Society a fee schedule was adopted which was to be ratified by the various county societies, and which was rejected by various county societies In San Francisco a mass meeting was held which resulted in a protest against binding ourselves to work for low wages As a result of this protest, the insurance companies have taken it on themselves to dictate who the physician shall be who shall treat the injured employees They have employed physicians at certain reduced fees, and have made contracts with physicians who would still further reduce their fees by giving a rebate of 25 to 30 per cent off of the schedule which had already been reduced 50 to 60 per cent

Dr. Mary Lawson Neff, Phoenix, Ariz I have been asked to speak on the psychologic aspect of the question I examined in Los Angeles a few days ago with Dr Allen a man, a jitney-bus driver, who had been arrested for charging at full speed into another automobile He proved to be a paretic, and from time to time in different clinics I have seen many such cases I believe if we collected them we would find an immense number of industrial accidents due to mental and nervous diseases I think also the question of mental defect should be given attention The high-grade mental defective is not recognizable except by a mental examination and not always then, but a great many mentally defective people find their way into industrial positions that they are quite unfit for The high-grade defective, for instance, is quite capable of working in a gang under a good foreman, but is incapable of working independently, and his right placing would depend on the proper psychologic examination, rather than the physical, that is, there are special defects that should be made the subject matter of psychologic work. For instance, a person with a "left hand lag" ought not to attempt to be a stenographer The person who is "ear-minded" is unsuitable for a telephone operator where a flash light signal is what she has to depend on for her work So it seems to me that there is a large field for the psychologist—the psychologist with common sense—in this department

Dr. Otto P Geier, Cincinnati I believe that this sort of work if well done in industry is going to stimulate the general practitioner to better work, more accurate diagnosis I find that we are continually coming across, as Dr McCurdy does, the mistakes and oversights in diagnosis on the part of the general practitioner, and after a while, when enough of this work has been done, it is going to become a very uncomfortable thing for the general practitioner to remain so slovenly in his diagnosis, and have his families find out from the industrial physician that he does not know his business It might surprise you to know that there have come before me, with only 1,000 men, three cases of appendicitis within the last six weeks, and two cases of tuberculosis. Those conditions we discover by virtue of the fact that medical inspection is insisted on, and because these men come freely to consult me just as they did their private physicians.

That matter then of the jacking up of the family physician, and making the general practitioner do less slovenly diagnostic work, I think, is going to be of some value

It is also going to help the man who is interested in public health work If he is interested in a larger budget for the health department, he should be interested in this thing, because if the people seize the idea that it pays to be healthy, they are going to see to it that the public bodies give the public health department more money In that way it is going to stimulate better health conditions in our cities

It is a question whether industries should undertake to do surgical work and medical service for its employees such as suggested by Dr McCurdy, because I think there is a little danger of pauperization, and I think we should steer very clear of this danger That of course should take care of itself by the inquiry into every man's social condition If he deserves it, give to him out of your industrial clinic the same service you give in the general public clinic In order to make this propaganda go with the profession we must steer clear of robbing the physician of his just part of medical and surgical service

Dr Sidney M McCurdy, Youngstown, Ohio It seems to me that a section on preventive medicine has a duty to perform in supporting the physical examination of employees The only active opponents that I can discover are the labor unions and they seem to be undergoing a change of sentiment We should help educate them to the fact that the examination is for honest purposes, and that no one will in the end profit more than the workingman

The question of psychology and its relation to a working force, I am much pleased to have brought out by Dr Rucker Our accident department finds that it can only prevent 35 to 40 per cent of accidents by mechanical devices, the rest probably belonging to the individual and to his psychologic attitude I have spent much thought and time in the endeavor to discover an accurate and rapid test for recording the mental condition of applicants for employment. Thus far I have not felt satisfied that any practical tests have been evolved

Lastly, I wish to thank Dr Warren for his most able paper on insurance I do not think that there will be any opposition from the employee when state insurance becomes necessary We have a relief association, not compulsory, to which 5,600 of our 8,000 men belong This would seem to indicate that the men appreciate the need of insurance and there is a real desire and necessity for a cheap form of protection I am a firm believer that while the medical fraternity may suffer a diminution in the size of its fees, for the ultimate good of society, state and national insurance for sickness and old age is the only logical solution of this problem

Dr. W F Snow, New York The purpose of offering my paper was to bring out, if possible, that there are moral and social hazards in industry as well as health hazards, and that the complicated interlocking of such hazards with those that we technically know as health hazards, makes it possible to attack some diseases in the reduction of their prevalence rather by an attack on these moral and social hazards than directly on the health hazards Venereal diseases are in this way sufficiently closely related to industry to demand close observation on the part of those working with health hazards in occupations

Dr John W Kerr, Washington, D C Much more might be said on this subject Its importance to the medical profession has been brought out this morning I would just like to emphasize its importance in relation to the public health movement, but I feel that health departments should be in closer touch, and that in future plans the work should be placed so far as possible in the hands of health departments [In order to give practical effect to the resolution already adopted Dr Kerr moved that a committee be appointed for the further consideration of this subject, to report at the next annual meeting This motion carried]

THE ROENTGENOGRAPHIC APPEARANCES IN RICKETS

WITH A COMMENT ON DIFFERENTIAL DIAGNOSIS *

ROBERT W LOVETT, M D

BOSTON

During the past winter between 6,000 and 7,000 roentgenograms from the records of the Children's Hospital were examined for the purpose of selecting from among them the plates of rickets, of which there were found between 500 and 600 These were set apart for a study which forms the basis of this paper This ratio of 10 per cent of rickets in the cases requiring roentgenographic study in the varied clinics of a children's hospital is of interest The plates of the general group covered cases of all types of trauma, congenital bone malformations, tuberculosis, scoliosis, osteomyelitis, empyema, scorbutus, osteomalacia, chondrodystrophia and syphilis

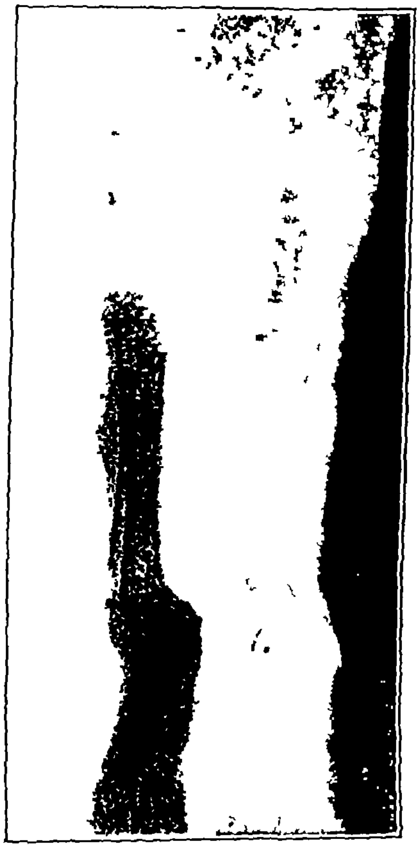

Fig 1 —Acute rickets First stage indistinct epiphyses, periosteal thickening, fractures

The plates of rickets were then carefully gone over several times from two points of view, (1) to establish and classify the Roentgen appearances of the acute, subacute and convalescent phases of the affection, and to define the finer bone changes associated with the disease, and (2) to determine definitely those points in differential diagnosis by which rickets might be distinguished from such diseases as osteomalacia, scurvy, congenital syphilis and similar affections

The research was originally undertaken to see if it was possible to determine from roentgenograms when the rachitic process had subsided sufficiently to make operative interference advisable in cases of knock knee and bow leg Experience had shown that such a determination by age limit was unsatisfactory, because even when children are 4 and 5 years old, one sometimes encounters soft bone offering little resistance to the osteotome, and in these cases profuse bleeding often results, suggesting that the rachitic process is still active

The study of the plates, however, proved so interesting with regard to the broader aspects of the disease that the inquiry enlarged itself into a comprehensive investigation of the Roentgen-ray phenomena of the disease in general A review of the literature proved that apparently such a survey was covering practically new territory

* From the Orthopedic Clinic of the Children's Hospital.

* Read before the Section on Orthopedic Surgery at the Sixty Sixth Annual Session of the American Medical Association San Francisco, June, 1915

Fraenkel and Lorey have contributed interesting material from which a Roentgen diagnosis of typical deformities can be made, but the finer aspects as to differential diagnosis are not given, nor is there any attempt to trace the stages of the disease through a definite Roentgen sequence

Von Recklinghausen's[2] study of pathology adds certain substantiating data to the roentgenologic evidences of the disease Koch's[3] work from the experimental biologic aspect of etiology is familiar in the recent current literature on the subject

There have been numerous French articles[4] dealing with the relation of rickets and syphilis, but as the literature in general does not bear directly on the aspect of the question under consideration, this paper will consist almost wholly of my own observations and conclusions

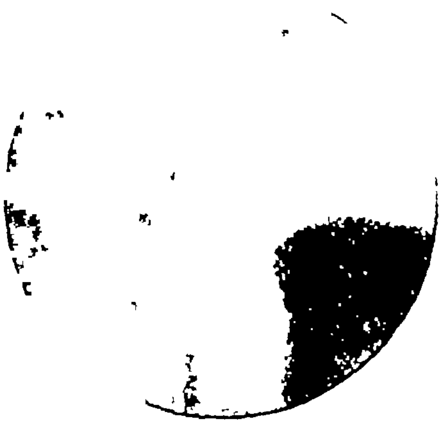

Fig 2 —Knee in acute rickets showing indistinct epiphyses and ragged diaphyseal ends with blocking off of lower end of shaft

On a comparative study of the plates, the disease divided itself naturally into three stages, stages in which the separation must of course be to some extent arbitrary, but which, on the whole, are distinct These apparently correspond to three stages based on anatomic pathologic data advocated by Guerin and Monti[5] as the stages of swelling and rarefaction, deformity and organization, healing and reparative eburnation

For this investigation, the knee was chosen as the most favorable joint for study The manifestations, however, are similar in other joints

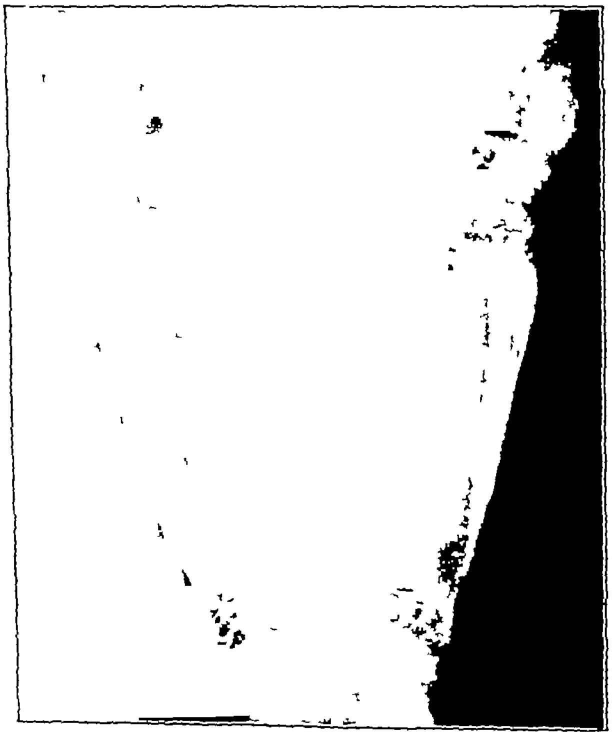

Fig 3 —Second stage epiphyses more ossified ends of bones broadening more marked on the side on which the strain is greater

FIRST STAGE

In the first stage there are two types, which differ in severity This stage is the early period of the disease, the period of onset and acute metabolic disturbance In the *milder* type, the ends of the diaphysis become frayed out instead of clear cut, and the epiphysis casts little or no shadow, while the center of ossification is small or absent, and at times appears multiple The whole joint is surrounded by a hazy cloud, and the diaphysis on the whole contains less lime than normal This is very marked in the juxta-epiphyseal region Up to this point deformities have not begun

In the *severer* type of the first stage, the epiphyseal appearances are similar, but more marked In the diaphysis, severe general bone atrophy exists, and there is pronounced periosteal thickening, associated as a rule with fracture of the bones, most often in the arms These cases of multiple fracture are very common, and are frequently classed as osteogenesis imperfecta, an affection wholly different in character Fraenkel and Lorey use the terms "florida" and "gravissima" in connection with these severer manifestations

SECOND STAGE

In the second stage, the shadow of the epiphysis becomes more marked The area is ragged and irregular about the margin, and calcification is more marked at some points than others, which results in a characteristic mottled appearance The ends of the diaphysis begin to broaden, especially on the side on which the strain is greatest, which produces a ledge or lip next to the epiphyseal line In bow legs this is found on the inner side of both the tibia and femur, and in knock knee on the outer side of the same bones This is the beginning of compensatory changes in the bone structure, which from all appearances are related to weight bearing

The diaphysis in the second stage begins to give a more definite shadow The region next to the epiphysis is streaked longitudinally, and is the area of maximum disturbance At the epiphyseal end of the shaft there is generally a transverse area of increased density reaching about a quarter or a half an inch from the epiphyseal line, bounded at the end furthest from the joint by a fairly sharp line This continues into the third stage, in which it may become more defined, and resembles in many respects similar changes observed in syphilitic bones in infants, described as osteochondritis, a point discussed under differential diagnosis

At the end of the diaphysis next to the epiphyseal line there often appears in the late second or early third stage a clear transverse white line, showing an increased deposit of lime in the lower end of the shaft This is apparently not to be distinguished from the "white line" which is described as a charac-

[5] Monti Rachitis Kinderheilkunde in Einzeldarstellungen 1900 ii.

teristic of scurvy, but which is equally characteristic of rickets[6]

Along the shaft of the long bones a longitudinal change occurs, which is compensatory in nature This consists in a cortical thickening on the concave side of the bones, chiefly noticeable in bones which have curved This change is of endosteal origin, and persists into the cured stage of the affection It is constant in curved bones, and is one of the most important characteristics in differential diagnosis

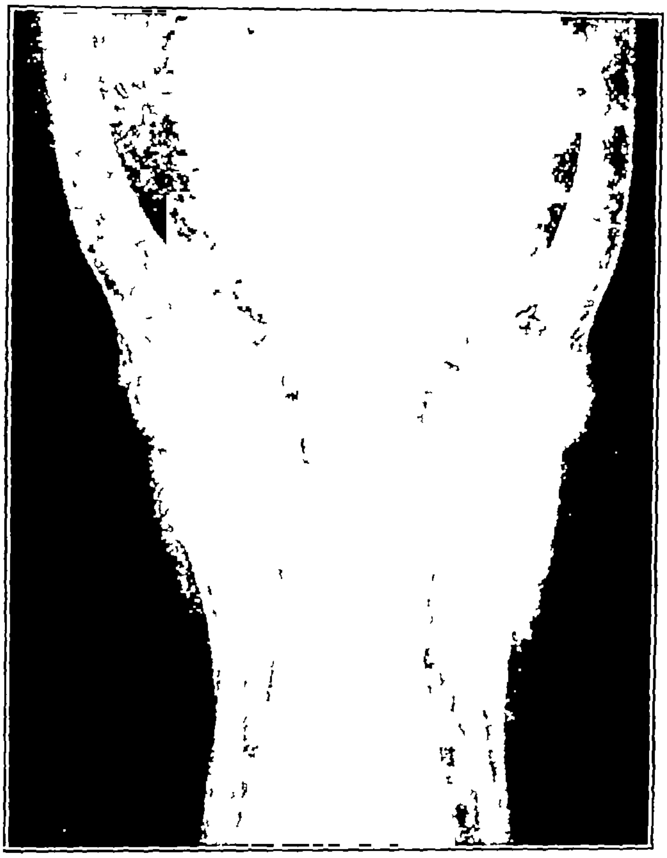

Fig 4—Second stage of rickets, showing returning ossification Note "white line" at ends of diaphyses described as characteristic of scurvy, chambering of lower part of femur

Further changes in the second stage consist in chambering of the interior of the bone, where light areas in the shaft indicate the absence of marked bone deposit, and heavier lines of ossification show the irregular development of trabeculae The smooth homogeneous shadow of normal bone is replaced by an irregularly streaked shadow structure

The second stage in general is a period of systemic reaction to the disease, in which signs of returning ossification occur and when deformity begins

THIRD STAGE

In the third stage, the epiphysis begins to resume its normal contour and homogeneous shadow density Irregularities persist in the marginal outline, and there is still a little mottling in the ossification The lipping of the diaphysis has enlarged the bone ends, and there is in consequence a discrepancy in breadth between the diameters of the diaphysis near the epiphyseal line and the epiphysis This relative difference in size is characteristic of this disease The clouded condition surrounding the joint in the earlier stages has gradually cleared away, and the bone shadows are more definite in consequence The white line mentioned in the second stage becomes more pronounced in the third

The other general changes are greater definiteness in the bone shadow throughout the shaft as well as in the joint, and the accentuation of the compensatory thickening of the shaft on the concave side of the curvature Though irregularities in the bone shadow continue, they are much less marked than in previous stages In the plates so far observed, the lower epiphysis of the femur seems to be the last to recover its normal outline, but a more extended general study would be required to establish this

The third stage is what may be termed the period of convalescence From this point on, the deposit of bone continues, the outline of the epiphysis becomes clean cut, and the epiphyseal shadows homogeneous and rather more than normally dense, and irregularities in deposition in the interior of the shaft become less marked

The characteristics of recently cured rickets are the enlargement of the diaphyseal end, which is not gradual but is a sudden lipping or ledging next to the epiphysis, the relative disproportion between the diaphyseal end and the epiphysis, and the cortical thickening on the concave side of the bone

For diagnostic purposes, therefore, the changes may be summarized as follows The epiphyses show scanty and irregular osseous deposit, and never have a clear normal outline during the acute process The end of the shaft is streaked, and presents an irregular line at the joint end and above it a curious transverse zone of different structure from the rest of the bone The interior of the shaft becomes chambered and irregular, and the whole shaft casts less shadow than normal The ends of the shaft broaden at the junction with

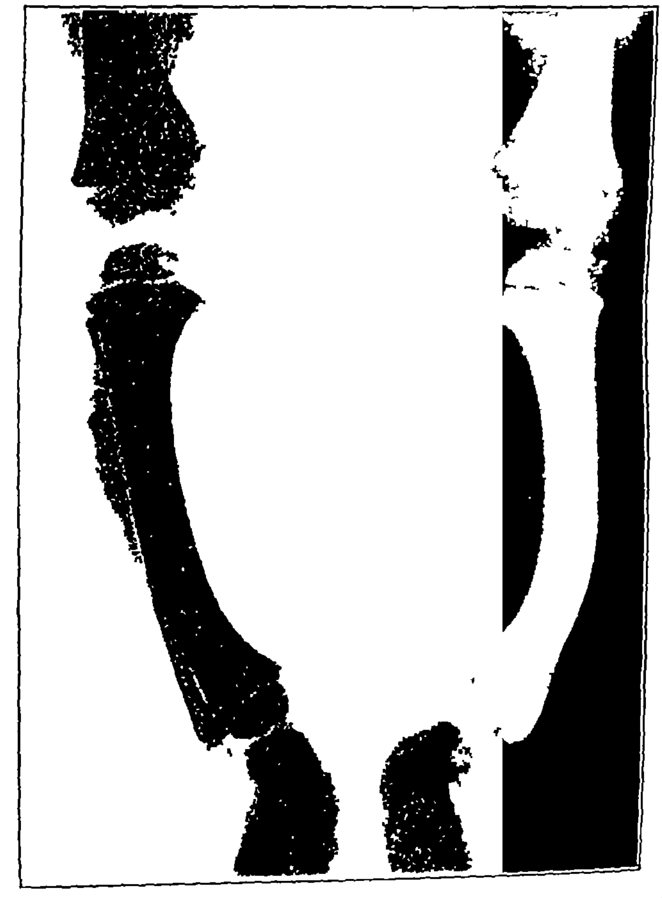

Fig 5—Third stage of rickets clear and ossified epiphyses, curved bones with compensatory thickening on concave side of curve, broadened ends of shaft at epiphyseal line, increased density of bone

the epiphysis, and throw out ledges on the side when strain is to be met A compensatory cortical thickening occurs on the concave side of curved long bones

[6] Talbot, Dodd and Peterson Experimental Scorbutus and the Roentgen Ray Diagnosis of Scorbutus, Boston Med and Surg Jour, Aug 14, 1913

DIFFERENTIAL DIAGNOSIS

In cases of scurvy, the roentgenograms show the clear outline of the epiphysis Even in cases in which extensive subperiosteal hemorrhage exists, with the attendant bone atrophy of the shaft and occasional dislocation of the epiphysis, the outline of the latter is quite distinct Atrophy in scorbutic cases, though at times extreme, is uniform The one point which is common to the two diseases in some cases is the white line occurring at the ends of the diaphyses On the condition of the epiphysis alone, however, it appears possible to differentiate the two diseases

In chondrodystrophia foetalis, the epiphysis is perfectly constant in maintaining its clearness and regularity of outline throughout the affection, and though the ends of the diaphyses are broadened, the changes occurring in this region in rickets, which have already been outlined, distinguish this part of the skeleton from chondrodystrophic deformities, which present comparatively uniform shadow densities

In hereditary osteogenesis imperfecta, one typical hereditary case has been studied very carefully through a period of eight years During that time there has never been any epiphyseal abnormality or disturbance in ossification at the ends of the diaphysis or elsewhere in the bones, although the Roentgen shadow of the bones is less dense than normal

The differential diagnosis between congenital syphilis and rickets from Roentgen-ray appearances is at once the most uncertain and interesting part of this comparative Roentgen study In this connection an extended study of plates of congenital syphilis was made, a study in which I had the invaluable help of my colleague, Prof Abner Post

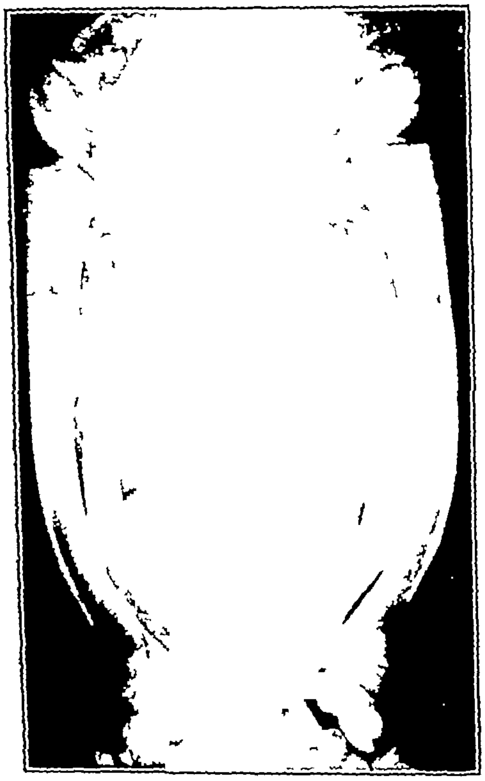

Fig 6—Side view of anterior tibial curve due to *rickets thickening is on concave side of curve*

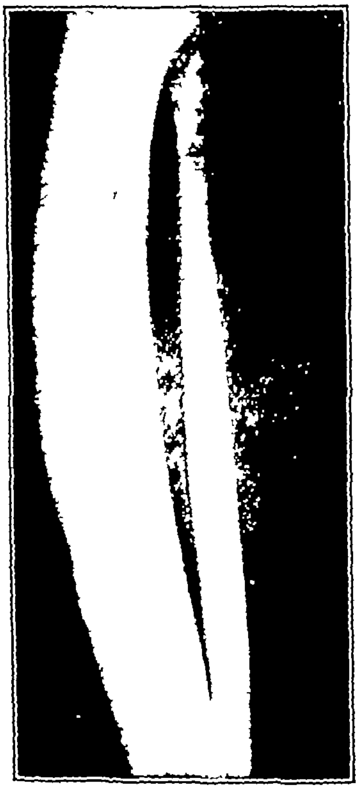

Fig 7—Side view of anterior tibial curve due to syphilis, thickening is on convex side of curve

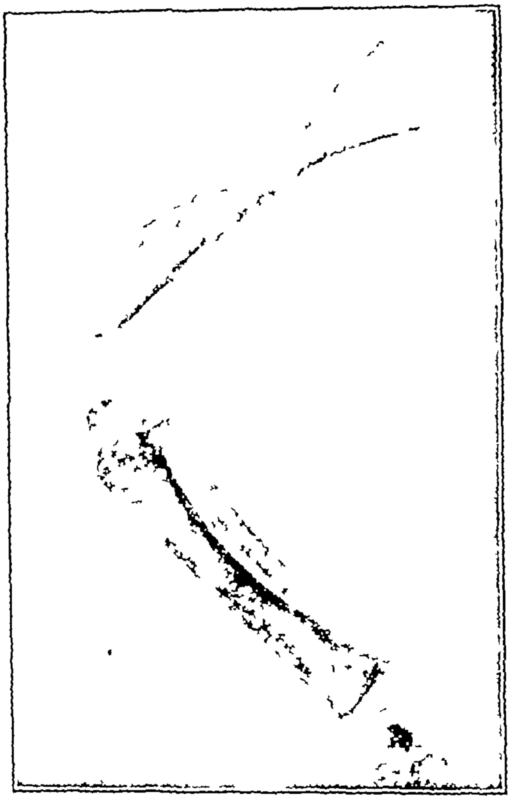

Fig 8—Side view of leg bones in congenital syphilis, showing periosteal thickening but distinct epiphyses. (After Fraenkel)

In children old enough to have acquired rickets, that is, in cases in which the question of differential diagnosis between these two conditions might arise, the epiphyses are far enough advanced in their development to be the focal point in the diagnosis The outline *of the epiphysis in* syphilitic cases is clear and not seriously disturbed as in rickets The appearance at the epiphyseal ends of the diaphysis of the zone of bone modification known as *osteochondritis in syphilis*, as has been said, is similar in appearance to the characteristic diaphyseal change in rickets In the latter, however, there is in addition to the absence or cloudiness of the epiphysis a marked enveloping cloudiness of the joint The time of the occurrence of this modification of the end of the shaft is also widely different In syphilis it is recorded chiefly in the fetus and the new-born, and of its later history we know practically nothing In rickets it occurs in the first dentition Extensive periosteal disturbance is common to the two diseases In the severe type of acute rickets in children with no syphilitic history or signs of syphilis, with a negative Wassermann reaction, severe periosteal thickening, very frequently associated with fracture, is found Such periosteal disturbance diminishes with the progress of the disease, and shows no tendency to bone formation such as is the case in the periostitis ossificans of syphilis Moreover, fractures are rare in syphilitic infants In the metacarpal bones this periosteal thickening is sometimes present in rickets presenting Roentgen-ray appearances of dactylitis, a subject now under investigation for future report.

The irregularities in the medullary shadow of the shaft in syphilis are due to irregular increases in density. The irregularities in rickets are related primarily to diminished density. In the later stages of both diseases the occurrence of cortical thickening is highly differential. In rickets the thickening is endosteal in origin, and is always on the concave side of the curve, while in syphilis the thickening is periosteal or osteoperiosteal, and is very uniformly on the convex side of the curve, resulting in the lower leg in the characteristic "saber tibia." This thickening in syphilis may occur on both sides, however. Further differential study of the two diseases is demanded, because they not infrequently exist in the same patient.

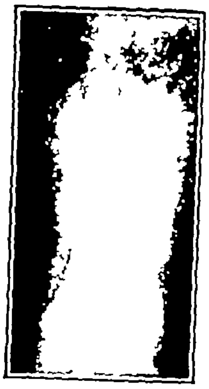

Fig. 9.—Osteogenesis imperfecta. Hereditary case under observation nine years.

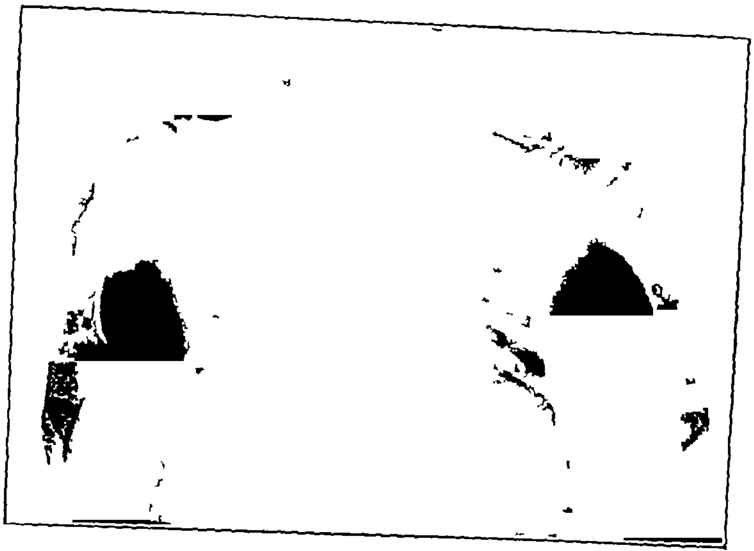

Fig. 10.—Chondrodystrophia foetalis. Broadening of ends of shaft, but distinct epiphyses.

SUMMARY

In rickets, constant changes are to be found while the disease is active, and are located most markedly in the epiphysis and the epiphyseal end of the shaft, but they also involve the shaft. The most important of these changes are (1) delayed ossification and indistinctness of the epiphysis, (2) fraying out of the end of the shaft next to the epiphyseal line, (3) broadening of the end of the shaft next to the epiphyses, (4) cortical thickening on the concave side of curved bones, and (5) areas of diminished density in the bone shadow of the shaft.

Periosteal thickening and multiple fractures often occur in the acute stage of the disease.

ABSTRACT OF DISCUSSION

Dr. Henry W. Frauenthal, New York: I know I am expressing the opinion of the gentlemen present that Dr. Lovett has given us a most scientific differential diagnosis of the various stages of rickets. But it is most difficult to differentiate between the late rickets and syphilis in our roentgenograms. I expect on my return home to review the plates taken at the Hospital for Deformities and Joint Diseases with added light from this valuable demonstration.

Dr. Roland Meisenbach, Buffalo: I should like to ask Dr. Lovett whether he has laid emphasis on the relation between the width of the epiphyseal line and the hardness or softness of the bone. For instance, in using the osteotome in bow legs or knock knees, we frequently find that in the wide and jagged epiphyseal line the deformity usually occurs near the epiphysis and the bone is spongy, whereas, in the deformities which occur farther away from the epiphyseal line the bone is relatively harder. The decision on a point of osteotomy often depends on the roentgenogram, as does also the feeding of the patient. It is interesting to see the changes in the rachitic bones, the effect of feeding, by means of the roentgenogram.

Dr. J. T. Rugh, Philadelphia: One thing which Dr. Lovett brought out is highly instructive to me. I do not know whether others have had the same understanding in regard to the deposits of bone in these rachitic cases that Dr. Lovett mentioned. I have always understood and taught that bone was deposited where strain took place just as Dr. Lovett said, and my understanding of the mechanics of these curved bones was that in a bone of this kind—a weight bearing one—the strain did not come on the concave but on the convex side. It is found that in practically all Nature, where there is weight bearing, the strain is on the convexity of the part. This is the part that is stretched. My understanding was that in these bones this was the part which was thickened, and in osteotomy or osteoclasis of these bones, this has been the part that always gave me the greatest amount of resistance with the osteotome. I must say this is a total reversal of my idea, and the Roentgen-ray plates which Dr. Lovett has shown bear out unquestionably his idea. I have seen specimens of bones, however, which have been classed as rachitic, in which a section showed the thickening to be on the convexity of the curve Possibly, as Dr Lovett has mentioned here, they may have been syphilitic bones instead of rachitic.

Dr. Robert W Lovett, Boston I do not agree with Dr Rugh's mechanics in this matter We are considering the question of weight bearing strains and I should suppose that the line of weight would be on the concave side and not on the convex side of the curved tibia

Dr. H R Allen, Indianapolis You refer to an operation, in which you have the strap arrangement on the outside

Dr. Lovett In regard to Dr Meisenbach's question, I believe we are operating too early in a good many cases of rickets I personally do not think any patient should be operated on until the lower epiphysis of the tibia, taking that as a standard, has become rounded with a clear outline. As long as it looks indistinct I think it ought to be left alone. At least, that is my experience When we do operate too early the bone is likely to bleed profusely and cuts like cheese. As a by-product of this investigation I have come definitely to the conclusion that those cases which Dr Meisenbach mentions are the ones that make the trouble, and that we ought to study our cases with the Roentgen ray and not operate until the subacute stage of rickets is over and the deposit of bone has begun again, because when they are in the subacute stage bones are very poorly provided with lime and are very soft. I thought that we should have a perfectly clear epiphysis before doing an osteotomy or osteoclasis The difficult point in the whole investigation is in the confusion with syphilis, and it is going to take hard work and exhaustive study to clear that up I believe the changes of rickets are definite in character and can be diagnosticated in the presence of syphilis, but even the best syphilographers do not know what becomes of the so-called osteochondritis seen in early life

PROLONGED AND ACCURATELY TIMED INTRAVENOUS INJECTIONS OF SUGAR

A PRELIMINARY REPORT *

R T WOODYATT, MD
W D SANSUM
AND
RUSSEL M WILDER
CHICAGO

The study of sugar tolerance and the effects of prolonged uniform injections of glucose by vein, of which this is an abbreviated report, was undertaken primarily for the purpose of perfecting an accurate clinical method for estimating the sugar-using powers of different individuals It was also anticipated that the data which would be obtained could not fail to have other applications, and that the method employed might be in itself of general interest as a means of studying problems of absorption, metabolism and elimination, and have therapeutic application Expectations concerning all of these things have been fulfilled

The study was based on certain prior ideas which were in part original and in part conceptions which had been expressed before by Doyon and DuFort in 1901, and by Blumenthal in 1906 These may be stated briefly

1 It is at present a common clinical practice to estimate sugar tolerance as the number of grams of glucose which can be given by mouth all at once and just fail to cause glucosuria, and having done so to draw inferences as to the power of the individual to *utilize* glucose But reflection will show that "tolerance" properly conceived as a measure of the power of the body to utilize glucose must depend on the rate at which the tissues are able to abstract glucose from the blood by their combined powers to burn it, to reduce it into fat or to polymerize it into glycogen It must be clear that this sum of three chemical velocities cannot be expressed in grams, nor yet in grams of glucose per kilogram of body weight, but that the element of time must be taken into account *Tolerance must be regarded as a velocity, not as a weight It must be measured and expressed in grams of glucose per kilogram of body weight per hour of time* or in other convenient units of weight and time

2 When sugars are administered by the stomach, the length of time during which they are actually brought to the cells must depend on the motor power of the stomach and of the bowel and on the rates at which the sugars can be absorbed, and even when they are given subcutaneously or by any other route which involves absorption as a prelude to their entering the blood, the rates at which they enter the blood will depend on the rates at which they are absorbed By any of these, but especially by the oral method, the actual rate of entry of sugar into the blood and tissues at large must vary with a wide range of physical, physiologic and pathologic conditions over which we have no control, nor will it ever be possible by such methods to force sugar to enter the blood any faster than it can be absorbed The rate of sugar absorption is a self-limited thing, for when a certain concentration of sugar is once present in the blood, no quantity given by mouth or subcutaneously or intraperitoneally can raise it higher In fact, if the concentration of blood sugar is raised above a certain point by intravenous injections, sugar passes out into spaces from which it would ordinarily be picked up, the absorption rate from these spaces then being expressible only as a minus value

3 *The nearest possible approach to a scientifically accurate method of sugar tolerance measurement must consist in direct intravascular administrations,* since only by this method is the variable factor of absorption rates reduced to a minimum When sugar is introduced directly into the circulating blood, each tissue receives its share in proportion to its vascularity, and absorption plays no part except as it may be concerned in the transfer of sugar from the local capillary to the perivascular lymph, and the taking up by each individual cell of the sugar with which it is bathed

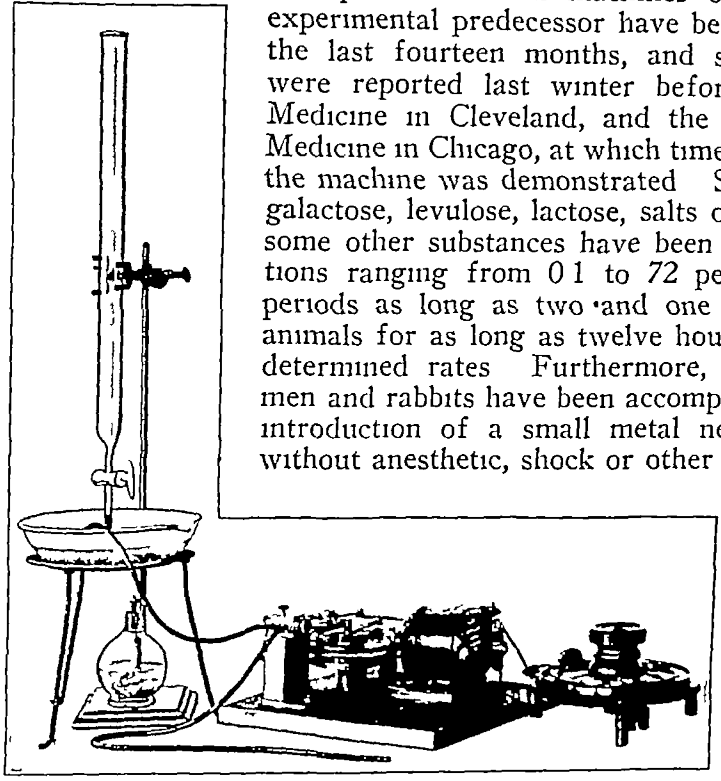
4 When glucose is introduced directly into a vein, we should expect different results with different rates of administration These different effects might be visualized by conceiving the body as made up of clear transparent tissues with blood like water, while the sugar injection is conceived as an injection of some red dye If the injection is uniform, continuous and not too rapid, we should first see the dye diffuse through the circulating blood, making the veins and arteries stand out in a deeply colored tracery in the otherwise transparent body Then the color would begin to "run" from the neighborhood of the capillaries, and, diffusing into the cells, would tint them —at first delicately and in some parts more than others as a histologic section absorbs the stain, then deeper and deeper until the whole mass of tissues were

---

* From the Otho S A Sprague Memorial Institute Laboratory for Clinical Research, Rush Medical College.

diffusely colored *This would take an appreciable time* Now if the injection is stopped, the color will gradually fade away as the sugar or dye is used up in the cells If the injection is begun again, the staining process will be repeated, and so on, the tissues alternately flushing and paling But if the injection rate is just equal to the rate of utilization, a uniform tint will be maintained indefinitely If the injection rate is faster than the rate of utilization, the color of the tissues will continue to deepen until they can stain no more, and finally the kidney, sharing in the general picture, drips the excessive stain, and, continuing to do so, the combined rates of excretion and utilization again just equal the rate of injection and the body again maintains steadily a certain depth of color, now of course deeper than before

It becomes apparent that to determine the utilization rate of glucose in the body, the problem is to find the greatest rate at which glucose can be injected into a vein steadily without causing any glucosuria, and following the foregoing analogy it is clear that the injection must be continued long enough to permit the sugar to diffuse uniformly into the tissues and bring each to its corresponding state of saturation before any conclusion is drawn as to what the final and permanent effects of a certain rate of injection really are It must also be apparent that a single syringeful of sugar solution injected all at once into a vein represents simply a very high rate of injection for a very brief period of time, and that such a method is the least capable of giving accurate information concerning utilization rates and the general behavior of intravenously administered sugar of any which could be devised Yet the literature is confused by many fallacious ideas which have been developed out of such methods



Apparatus for intravascular administrations On the right is the quantitative intravenous pump with rheostat for motor speed control the solution is drawn from a buret which may be more slender than that shown, and fitted with a side neck leading to a second buret of large capacity to facilitate refilling The rate of injection is checked at intervals by readings on the buret, and corrected if necessary by touching the rheostat The flame and bath on the left warm the solution The delivery tube lies in front

With these principles in mind, we have devised machines for the purpose of giving uniform intravascular administrations at precisely controlled and predetermined rates and for long periods of time

DESCRIPTION OF APPARATUS

The machine consists of a glass syringe barrel with a metal piston provided with a piston ring (record syringe), the barrel being fixed while the piston is actuated by a piston rod from an eccentric on a power shaft The latter is driven by an electric motor through a worm and gear which reduces the speed of the motor and increases the power correspondingly On the nozzle of the syringe there is a two way all metal valve of special design which is turned automatically by a cam shaft and alternately permits an influx and outflow of fluid to or from the pump barrel The rate at which the machine delivers fluid is controlled in three ways first by the size of the barrel, which is interchangeable so that any capacity can be used from 0 5 to 10 c c , second, by a device which regulates the stroke of the piston to any desired length from a millimeter up, and, third, by a rheostat with which the motor speed can be controlled delicately while running so that the pump makes any desired number of strokes per minute between 15 and 60

The machine is intentionally provided with a surplus of power It is heavily built and of a high grade of workmanship It pumps precisely and relentlessly anything from water to an 80 per cent glucose syrup, at any rate from 10 c c to 5 liters hourly, overcoming with negligible variations in speed any minor obstructions which may occur in the tubing or the intravenous cannula or needle All parts which come in contact with the fluid to be injected are detachable and sterilizable A photograph of the machine is here reproduced

Experiments with machines of this type and an experimental predecessor have been conducted during the last fourteen months, and some of the results were reported last winter before the Academy of Medicine in Cleveland, and the Society of Internal Medicine in Chicago, at which times an earlier model of the machine was demonstrated Solutions of glucose, galactose, levulose, lactose, salts of various kinds and some other substances have been given in concentrations ranging from 0 1 to 72 per cent to men for periods as long as two and one half hours, and to animals for as long as twelve hours, at precisely predetermined rates Furthermore, the experiments in men and rabbits have been accomplished by the simple introduction of a small metal needle into the vein without anesthetic, shock or other nonphysiologic factor For dogs we have employed a small blunt needle provided with a flange, or a very small cannula which was introduced into the saphenous vein under novocain

The results so far obtained have led us to believe that timed intravenous injections of solutions of known concentration over long periods of time offer a most valuable method of studying a wide range of problems of absorption, kidney function and intermediate metabolism They also promise to extend the possibilities of intravenous injections for diagnostic and therapeutic purposes beyond anything which has been accomplished heretofore Some of the principal results may be mentioned briefly in this place

EXPERIMENTAL RESULTS

1 A normal rabbit, dog or man can utilize between 0 8 and 0 9 gram of d-glucose per kilogram of body weight and hour of time without glucosuria for an indefinite time, that is, d-glucose in 10 to 50 per cent solution can be introduced directly into the veins at rates corresponding closely to 0 85 gram of glucose per kilogram of body weight and hour of time for from six to twelve hours and not produce any glucosuria Such rates of glucose administration do not cause any effect which can be interpreted as diuresis

These facts force certain conclusions, some of which may be mentioned

(*a*) A man weighing 70 kg, when resting quietly in bed, may receive and utilize 63 gm of glucose by vein per hour without glucosuria (This is an accomplished fact) He then receives 4 times 63, or 252 calories per hour, a rate corresponding to 6,048 calories per day If his resting requirement were 3,000 calories per day, he could thus receive double what he needed, or enough to cover the caloric expenditure of the same man during heavy physical exertion *Intravenous nutrition with glucose is thus proved to be a feasible clinical proposition*, and the way is opened for experiments with amino-acids, polypeptids, etc

(*b*) The normal tolerance limit for glucose, expressed as a velocity, is established at close to 0 85 gm glucose per kilogram of body weight hourly, which agrees approximately with what Blumenthal has established by repeated small intravenous injections in animals

(*c*) The idea, already in part discredited by the work of Pavey and Godden and others, that the "glycogenic function of the liver" is indispensable for the utilization of glucose, or that it is in any sense necessary as a *barrier* to prevent sugar absorbed from the bowel from being lost in the urine, is definitely laid at rest

(*d*) The idea that any large quantity of glucose given by vein always causes glucosuria and diuresis is an error based on clumsy methods of study

2 The intravenous tolerance limit in cases of exophthalmic goiter has been found as low as 0 65 gm per kilogram and hour, but two cases of acromegaly had a tolerance of 0 85 gm per kilogram and hour, which is not above the normal, although by the oral method it had not been possible to cause glucosuria with glucose

3 The tolerance limit for levulose when given by peripheral vein has been found close to 0 15 gm per kilogram and hour, or only one-sixth that of glucose For galactose it is even less or about 0 1 gm per kilogram and hour For lactose it approaches 0, as known before

4 When glucose is given by vein faster than at the rate of 0 9 gm per kilogram and hour, glucosuria appears, then usually a little later, diuresis When the rate of injection exceeds the normal utilization rate, the time which elapses before glucosuria appears varies If the injection rate is much too fast, the elapsed time is correspondingly short, or if the tissues have previously been partly saturated with sugar, the same applies If the injection rate exceeds the utilization rate by about 0 1 gm per kilogram and hour and the tissues happen to have been low in sugar, it may require several minutes of injection before glucosuria begins But if a given rate of glucose injection causes glucosuria at all, it always begins to do so within the first half hour The same general principles apply to other sugars with lower rates of injection

5 As the rates of glucose injection are increased above 0 85 gm per kilogram and hour, the rates of overflow in the urine increase also according to definite mathematical laws At any given rate, say for example 1 8 gm per kilogram and hour, the glucosuria begins slowly, increases in a steep curve, and finally becomes constant at some level characteristic for this rate of injection The height of this level, of course, is higher in the case of the more rapid injections and lower for the slower ones Also the time which elapses before the level is established is the greater the higher the level to be attained It frequently takes from three to four hours for a glucosuria due to a uniform glucose injection by vein to reach its constant level

As already stated, about 0 85 gm glucose per kilogram and hour may be given indefinitely without glucosuria If we give twice this quantity in the same time, that is, 1 7 gm glucose per kilogram and hour, there is glucosuria which, when constancy is attained, averages about 0 17 gm per kilogram and hour This confirms the older view of Carl von Voit, proved to hold for sugar by Lusk, and Fisher and Wishart, that *increasing the concentration of the food in the tissues* increases the rate of utilization But if glucose is given at a rate faster than 2 gm per kilogram and hour, a large percentage of all glucose in excess of the 2 gm per kilogram and hour appears in the urine, once constant conditions have been secured

In a normal individual, the greatest rate of glucosuria which can be produced by feeding any quantity of glucose by mouth is limited, and at most approximates that which is produced by an intravenous injection at the rate of 1 8 gm per kilogram per hour Hence it would be reasonable to believe that when sugar is given by mouth in health, it is never absorbed faster than at this rate This method of estimating an absorption rate by finding a rate of direct intravenous injection which just produces the same effect is, so far as we know, new, and it should be applicable to other problems

6 As glucose is given at rates exceeding 0 85 gm per kilogram and hour, and unburned glucose begins to accumulate in the tissues and pass out chiefly in the urine, it carries with it water With rates of injection only slightly exceeding 0 9 gm per kilogram and hour, the amount of sugar which escapes burning is moderate, and so the rate of glucosuria and the rate of diuresis are correspondingly moderate But when sugar is given at the rate of 5 4 gm per kilogram and hour (that is, 54 gm hourly for a 10-kg dog), this is equivalent to giving about 3 6 gm per kilogram and hour over and above what can be burned It is like giving 3 6 gm per kilogram and hour to a total diabetic

The effect is an incredibly great diuresis When glucose is given at this rate to a 10-kg dog, the urinary output rises rapidly to the vicinity of 350 c c per hour If each hour the dog receives enough water to make good the losses, the rate of diuresis or a higher one can be maintained for long periods of time A 10-kg dog actually passed in eight hours 2,800 c c of urine This would correspond to 19,600 c c for a man weighing 70 kg in the same time, or an hourly rate of 2,450 c c If enough water is not given to counterbalance the urinary water losses, the volume of urine falls and the dog suffers from thirst Death may be caused in this way Unless plenty of water is given, not all of the unused sugar can leave the body, since it appears that the concentration of glucose in the urine will not rise above 12 5 per cent To make 12 5 gm of glucose pass out of the body through the kidneys, at least 100 c c of water are necessary On the other hand, if one gives too much water with the hourly glucose injection rate of 5 4 gm per kilogram and hour, there is danger of stopping the heart mechanically We have produced a diuresis as high as 600 c c per 10 kg of body weight for one hour, and still greater rates are possible, but attempts to continue such enormous water traffics lead to heart failure This rate would correspond to an output of 4,200 c c of urine hourly from a man weighing 70 kg, or 100 liters in twenty-four hours *In giving intravenous injections of glucose there are then two things to avoid too great dehydration on the one hand, and heart failure from imposing too much mechanical work on the other These can both be avoided by knowing the number of grams of glucose which enter the body hourly, and what volume of water is moved by such a rate of sugar injection*

CLINICAL APPLICATION

It is hardly necessary to emphasize the therapeutic possibilities which these experiments suggest With a knowledge of the proper concentration of the solution to be used, and the rate appropriate for this particular solution, we may (1) abstract any quantity of water from the body which we deem safe or desirable, or we may (2) pass through the body a great flushing stream to wash out poisons How far the principles worked out for normal individuals will apply in disease we have only begun to learn In this connection it may be well to recall that the literature already contains observations on the use of sugars in therapeutics

Sugars have been given by mouth or bowel for purposes of nutrition or to obtain other desired metabolic or chemical effects in a wide range of clinical conditions But as pointed out, such methods of administration do not introduce sugar into the blood faster than an approximate rate of 1 8 gm per kilogram and hour at most, which is not sufficient to permit much glucose to escape utilization Hence, after such administrations, unburned sugar does not accumulate in the tissues except to a limited extent, and they are not diuretic except in cases with decreased rates of sugar utilization (diabetes) Intravenous injections may exceed this rate, and so cause, in addition to the ordinary chemical effects of glucose, new physicochemical effects due to the presence of unburned sugar molecules in the tissues, and expressed outwardly as diuresis Now glucose and levulose have long been found useful when given in cases of diabetic coma, especially when given intravenously In such cases either mode of administration produces great diuresis, but especially levulous by vein (for levulose the *normal* intravenous tolerance limit being only 0 15 gm per kilogram and hour) It has not yet been recognized that the value of this treatment is due to the diuresis, but we have on other occasions given the reasons which make us believe that this is the case In 1907, Fleig[1] made roughly timed intravenous sugar injections, was struck by the remarkable diuresis, and realized possible clinical applications, without making any, however Kausch,[2] in 1911, recommended and attempted intravenous nutrition with glucose in hysterical vomiting hyperemesis gravidarum, surgical conditions and acute gastro-intestinal disease, but laid no emphasis on the diuretic action Fischer[3] recommended intravenous glucose injections in conditions of edema, nephritis and intoxication; but especially oligurias and anurias of various sorts on the basis of his observations concerning the power of sugars to dehydrate colloid gels and on their parallel diuretic effects in rabbits and men, thus bringing the behavior of sugars in these respects into relationship with that of diuretic salt solutions and recognizing the physicochemical principles which underlie the beneficial effects of intravenous injections of sugar In 1914, Henriques[4] reported the use of from 250 to 300 c c of 30 per cent glucose solution in the hour to about fifty clinical cases of heart disease, intoxication, and severe infections, finding special indications in oligurias of nephritis and heart disease He did not discuss the principles involved This year Turrettini[5] has given details of three cases of acute nephritis and three of mercuric chlorid poisoning, in all of which the urinary output was favorably affected Experiments have been in progress in this laboratory for some time to determine the limits of application of these principles and the present technic of administration to different grades of experimental poisoning with mercuric chlorid, arsenic and diphtheria toxin The system is being tested in the clinic as opportunities offer Its chief application would appear to be in acute intoxications of various sorts, acute oligurias and anurias, intoxication of pregnancy, and in cardiac and other edemas Further work is in progress on other diuretics besides sugars and on other sugars besides glucose, and also with simultaneous injections of sugars and salts, such as acetates and bicarbonates

SIGNIFICANCE AND PREVENTION OF AMEBIC INFECTIONS IN THE MOUTHS OF CHILDREN *

ANNA WESSELS WILLIAMS, M D
ANNA I VON SHOLLY, M D
CAROLINE ROSENBERG, M D
AND
ALICE G MANN
NEW YORK

From time to time during more than half a century, a protozoan genus called *Ameba* by some, and *Endameba* or *Entameba* by others, has been reported as occurring chiefly about the gum margins in the oral cavity of human beings

Few details of the morphology, comparative incidence and pathogenicity of the members of this genus have been given Until last year, most, if not all of the species, were thought to be nonpathogenic Indeed, of so little worth were they considered that no mention of their presence is made in the general histologic review of parasitic amebas of man by several authors, who used the term "parasitic amebas" as synonymous with "intestinal amebas"

Thus Craig says

> There is no experimental evidence connecting *Ent buccalis* (or the mouth ameba) with disease It is very doubtful if it has anything to do with caries of the teeth, although it is most frequently encountered in the cavities of carious teeth However, it may be frequently demonstrated in material scraped from the roots of perfectly normal teeth so that, as far as the evidence goes, we must regard *Ent buccalis* as only a secondary invader The amebae known as *Ent gingivalis*, Gross, 1849, and *Ent dentalis*, Grassi, 1879, are probably identical with *Ent buccalis* and do not merit separate description

* From the Bureau of Laboratories, Department of Health, New York City

* Read before the Section on Preventive Medicine and Public Health at the Sixty Sixth Annual Session of the American Medical Association, San Francisco June 1915

In 1914, Smith and Barrett, followed by Bass and Johns and several other investigators, asserted that mouth amebas occurred chiefly in cases of pyorrhea alveolaris or Riggs' disease, and that they were the probable cause of this common septic infection of the jaws Other observers have not agreed with this assertion because sufficient evidence has not been given by its authors to make us sure of the types of amebas found and of the extent, if any, of their pathogenic action So several hypotheses may be formulated as to the part thought to be played by amebas in mouth infections

HYPOTHESES IN REGARD TO ACTION OF AMEBAS IN HUMAN MOUTHS

1 Amebas are accidental invaders, they produce no pathogenic or other reaction in the mouth (Provazek Hartman and others)

2 Amebas in the mouth have a beneficent action as scavengers (Chiavaro and others)

3 Amebas may be sometimes pathogenic, producing or helping to produce certain cases of pyorrhea alveolaris, certain abscesses and certain other mouth infections (Leidy, Gross, Flexner, Smith and Barrett and others)

4 Amebas are the specific cause of pyorrhea alveolaris (Bass and Johns and others)

5 Amebas may be pathogenic only in connection with certain other micro-organisms

The comparative worth of these hypotheses may be discussed as follows

In favor of the first hypothesis, that is, that amebas are accidental, nonpathogenic invaders, are the facts that amebas have been reported so frequently in apparently normal mouths and that when found in diseased conditions, they are always accompanied by other micro-organisms of pathogenic types, which might be sufficient to produce the disease Against it is the fact that they are found so much more frequently and in so much larger numbers in the lesions

As for the second hypothesis, that amebas are beneficent scavengers, there is no question but that amebas are scavengers both of other micro-organisms and of tissue host cells — at least, of leukocytes, red blood cells and broken down epithelial cells But they probably take up as many harmless as well as harmful germs and leave enough of the latter to exert their full power in harming the tissues of the host Then, too, since we know that certain amebas will live on brain, liver and kidney cells of human beings, there is no *a priori* reason to suppose that the mouth amebas will not help in destroying the fixed tissue cells in the mouth, especially after a certain amount of injury has been done them by other micro-organisms The evidence, then, is against this second hypothesis as it stands

As regards the third hypothesis, that amebas are sometimes pathogenic, we can only say that the large number of amebas in most cases of pyorrhea and in some abscesses of the jaw, and their infrequent presence in absolutely healthy mouths make this a tenable hypothesis

We may state, concerning the fourth hypothesis, that is, that amebas are the specific cause of pyorrhea alveolaris, that whether or not they are the specific cause of this condition can only be determined after further study Some facts brought forward in this paper bring new evidence on this point

In regard to the last hypothesis, that is, that amebas may be pathogenic only in connection with certain other micro-organisms, we must remember that if amebas absorb and digest fixed tissues as well as leukocytes, blood cells and other wandering cells, they may help decidedly in keeping up a lesion bacteria have started This fifth hypothesis is also tenable

ORIGINAL WORK

In order to help determine which, if any, of these hypotheses is correct, we have been trying to find out, first, how many children are infected and at what age the amebas begin to appear in their mouths, as well as to study the condition of the mouths showing the amebas Second, what types of amebas, if more than one, are present Third, the relation, if any, of these amebas to the diseased condition of the childrens' mouths, and fourth, the necessity and worth of preventive measures

We have begun our study by examining the mouths of the schoolchildren in one of the poorer districts of New York City We have already started the examination of a similar group in one of the more well-to-do districts At the same time, the Bureau of Laboratories of the New York City Health Department has begun a more general study of focal mouth infections, particularly of pyorrhea alveolaris

Soon after our observations on adults were begun, we found that all patients presented to us by the several dentists who are collaborating with us already had pus pockets formed in the jaw alveoli — that is, they were well-established cases — and when we began to inquire for beginning cases, we learned that the diagnosis of pyorrhea alveolaris is made by most dentists only after pus pockets can be demonstrated, so this added interest to our decision to hunt for beginnings in schoolchildren

So far 1,678 children (those in only one session of the school) between the ages of 5 and 15 years have had a preliminary examination, and from 995 representative ones stained smears have been made and examined for amebas The 1,678 children have been divided roughly into those having healthy gums and those with receding or spongy and bleeding gums The healthy looking gums are further divided into those with one or more decayed teeth, and those with apparently sound teeth Needless to say, we found very few of the latter, that is, of those with apparently healthy gums and sound teeth, and about one half of all showed unhealthy gums

From many cases, two smears were taken The smears were made as follows In the bad cases, the teeth and gums were cleaned with a cotton swab dipped in 50 per cent alcohol, then with the flat end of a hard wood sterile toothpick, material was scraped from the margin of the gums (there were no pus pockets in these children, so we did not need a scaler) and stroked lightly over a clean glass slide, three or four streaks being made The smear was then fixed while still moist by dropping methyl alcohol on it, and it was ready to send to the laboratory This was called the superficial smear A second toothpick was used to get material from beneath the margin of the gums, from which another smear was made and fixed This was called the deep smear In the cases with clean teeth and tight healthy looking gums, the first smear was made before the cleaning with alcohol All of these smears were stained with Giemsa's stain and examined for amebas Other stains have also been used in the more minute study of types of amebas In regard to the identification of amebas by stained films, we would say that they are more certainly and easily identified by this method than by warm living preparations, though, of course, both methods should be used in studying all of the characteristics of these micro-organisms In hunting for amebas in these smears, we have found that most of them seem to be between he superficial bacterial layer and the deep leukocytic layer, so one may find them only in large numbers in one small part of a smear, especially in a smear taken in a routine way

Stained by Giemsa, the delicately but definitely reticulated cytoplasm of the ameba stains a clear blue, while the small nucleus shows as a delicate rounded or irregular mass of red granules and threads, with often a central light blue staining karysome which sometimes contains a vacuole-like body This nucleus no doubt corresponds to that most frequently described for *Endameba histolytica-tetragena* There has been found no marked variation from this type of nucleus

Amebas are so notoriously variable in their entire morphology, according to their stage of development, and to the conditions of growth, that no definite opinion should be expressed as to the species of the forms found in these mouths until much further study has been made We may say, however, that there seem to be at least two morphologic types of amebas present one small, with more or less rounded, dense nucleus, with a few or no inclusions or vacuoles, found in the majority of healthy mouths, and the other large, with more irregular nucleus with many large vacuoles and containing many red blood cells, leukocytes and other dense masses formed by undigested material The latter type is found in the majority of unhealthy mouths Its appearance agrees with that of the type most frequently seen in the well-developed cases of pyorrhea alveolaris We have seen no cysts We have seen evidence of budding and of more equal division

NUMBER AND PERCENTAGE OF AMEBAS FOUND IN EACH GROUP OF CHILDREN

Condition of Mouth	Between 5 and 16 Years			Between 5 and 7 Years		
	Total		Amebas Present	Total		Amebas Present
1 Healthy gums	(+ 38) (— 92)	=	29 per cent.	(+ 3) (— 31)	=	9 per cent
2 Healthy gums decayed teeth	(+109) (—183)	=	37 per cent.	(+ 32) (—105)	=	23 per cent.
3 Tartar and receding gums	(+182) (— 96)	=	65 per cent	(+ 19) (— 17)	=	53 per cent
4 Spongy bleeding gums	(+268) (— 28)	=	91 per cent.	(+ 34) (— 5)	=	70 per cent

We have found that amebas begin to appear at a very early age, 35 per cent of children between 5 and 7 years of age being infected The numbers of those infected with amebas increase in frequency with age Between 5 and 15 years, 60 per cent show these protozoa on their gum margins In apparently normal mouths, only 29 per cent show amebas Taking the percentages by groups as in the accompanying table, the results are more significant

Finding the amebas so often in apparently healthy mouths and in such young children does not agree with the statement of Bass and Barrett that they are not found in healthy mouths Whether or not one or more varieties are taken from adult pyorrhea patients and are simply waiting their opportunity to exert a pathogenic action, we cannot yet say But the evidence seems to point toward the establishment of either the first or the fifth hypothesis already given

These results, however, as they stand, are very striking, especially when we must add that most of the cases of spongy and bleeding gums show more amebas in the films than the other cases If we could only rule out other micro-organisms, the evidence for the pathogenic action of the amebas would be stronger

We have, in these schoolchildren carriers of amebas, a marked opportunity to test the prophylactic effect of ipecac or its emetin alkaloid on mouth amebas

We have divided the cases showing amebas into three groups, one to be watched without treatment, and others to be treated in different ways, one with emetin and the other by ordinary cleanliness We have a tooth wash made up containing a dilution of emetin, and have the washing of the teeth done morning and afternoon in the school clinic under the supervision of the school nurse

The first examinations, one week after the beginning of this treatment, gave marked results, in that every child but one, receiving emetin, showed no amebas, while many of the others showed them In the later examinations, however, amebas were found in a few of the emetin-treated which were negative before, while a few more of the controls showed none

The following points have been brought out so far by these examinations

Amebas are demonstrated irregularly in all mouths once showing them, most constantly and in largest numbers in mouths showing gingivitis, least so in healthy mouths

With ordinary teeth cleansing methods, the number of mouths showing amebas is reduced one half With emetin in the tooth wash, the number showing amebas is greatly reduced, only about 10 per cent showing them The second set of controls — those doing their cleaning *at home* by ordinary methods — continue to show amebas in about 75 per cent of the cases

The question as to the amount of emetin to be used has not yet been settled We began with a 1 200 solution, then reduced it to a 1 400 strength Probably a much smaller amount would be sufficient to keep down the development of the amebas

We hope to carry on these investigations for several years and, if necessary, to extend the number of children included in the groups Whether or not we can demonstrate fully the efficiency of the use of an amebacide in preventing many cases of pyorrhea alveolaris remains to be seen We hope by combining these practical investigations with the laboratory studies that we may be able to help demonstrate the relationship of these amebas in septic mouth infections

ABSTRACT OF DISCUSSION

Dr. Woods Hutchinson, New York It is an interesting and important subject, especially in view of the effect of the organisms involved in later life. My impression is that we shall find that the diseases of the gums in later life bear the same relation to the infections of childhood that the diseases of so-called middle age do to the infectious diseases of younger life We elderly individuals, who ought to be Oslerized probably, are beginning to be terribly worried about diseases that attack us over 50 By taking proper steps we may very early remove the cause of our worries

The ameba in its relations with the pathogenic organisms may prove to be the keynote of the diseases and loss of teeth at an immature and undesirable time

Dr. C. C Bass, New Orleans I do not know of any other series of cases as large as that reported by Dr Williams Most examinations that have been reported and come to my attention have been in older people, practically all of whom were infected The study, then, of Dr Williams and her associates is especially valuable because it takes up the subject of the disease at a stage at which it could be prevented perhaps whenever we know enough about it, or cured before too great damage is done As to the pathogenicity of the amebas that we find in the mouth and in pyorrhea lesions the evidence at hand leaves the question somewhat open Many good authorities are confident that this ameba is not the cause of pyorrhea and does not play a part at all. Others are willing to grant that it may play a part Still others including ourselves feel certain that the chief specific cause of alveolodental pyorrhea is *Endameba buccalis* One of the things that we have observed we believe as certainly as any other thing is that these endamebas feed on certain nucleated cells that are to be found only in inflamed tissue If we make sections of the diseased tissue we find these same cells distributed not only on the surface, but actually in the inflamed tissue. Now for endamebas to get these cells they must crawl about or burrow about in the inflamed tissue searching for them We have been able to demonstrate and find the endamebas in the tissue and determine to what extent they burrow We find that they burrow for a distance many times their diameter, but possibly they do not burrow as deeply as the endamebas in amebic ulcers of the intestine do Not only do we find them in the tissue but we find them also on the surface of the closed ulcerated tissue in the bottom of the pyorrhea pocket In burrowing back and forth from the pyorrhea pocket and then into the tissue many different species of bacteria are transported or transplanted and retransplanted by the amebas Whether endamebas are present in all cases of pyorrhea we will be obliged to wait for further studies to determine until those working on the subject have acquired such technic as will permit them to make accurate negative diagnoses It is quite difficult to make an examination which justifies one in saying positively that the individual has not some endamebas present We may say he has no endamebas demonstrable by our technic but a microscopic lesion may be large enough to hold many endamebas We cannot give a mouth a casual macroscopic observation, and determine that there is no inflammation of peridental membrane around or between any of the teeth The disease begins between the teeth, where it cannot be seen After it is advanced, then we may see evidence of the disease labially or lingually It is difficult if not impossible to determine that an individual has a normal mouth The fact that some endamebas have been found and are found in what are called apparently normal mouths cannot be taken too seriously on this account. Our experience has been that in the examination of probably 500 individuals having pyorrhea we found endemebas in all of the patients after we had acquired the technic which seems to us quite necessary

Dr. Anna W Williams, New York Just such work as Drs Bass and Johns are doing in histologic biology will no doubt be of much aid in helping us to get more evidence in regard to the relationship of this organism to disease. In regard to the use of the toothpick, I would say that we simply use a toothpick in our routine examinations of the schoolchildren These children do not need a scaler since they do not have pus pockets We have only found one of the older boys having small pus pockets We use Young's dental scaler No 22 for obtaining material from the adult pyorrhea cases that we have studied

COMPLEMENT FIXATION IN DIAGNOSIS WITH BACTERIAL EXTRACTS PREPARED WITH DIGESTIVE FERMENTS

J O HIRSCHFELDER, M D
SAN FRANCISCO

In a preliminary report[1] in The Journal a method was described by me for the preparation of a soluble vaccine against the pneumococcus, and the evidence presented of its efficacy in producing active and passive immunity Ten cases of pneumonia treated with the extract were tabulated and reference was made to experiments with other micro-organisms Since then, extracts have been prepared with greater accuracy by improved methods and the immunizing effects have been made more constant At the same time, it has been found that these extracts are valuable as antigens in complement fixation for diagnostic purposes

PREPARATION OF EXTRACTS

As the standardization of bacterial suspensions by the known methods of counting is notably uncertain, a gravimetric method was devised based on their opacity as compared by means of a delicate photometer with that of a suspension containing a known quantity of the micro-organism as determined by its weight when dried at 110 C. The germs were grown in bouillon that had been passed through a Berkefeld filter and then autoclaved After growth, the culture was filtered through a Berkefeld and the germs washed several times with distilled water The bacteria were then gently rubbed off under a fine stream of distilled water with absorbent cotton on the end of a wire and the suspension well shaken

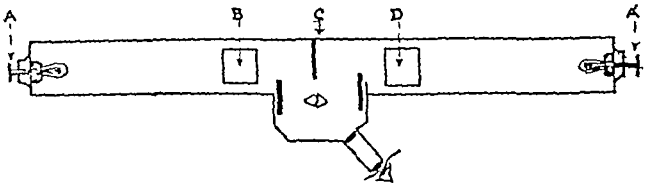

Diagram of light for determining amount of micro-organisms in suspensions See full description in text *A A* screw adjustment for lamp *B* standard bottle *C* Lummer Brodhun photometer *D* test bottle

A portion was weighed and dried at 110 C and the dry weight determined. Weighed portions of the suspension were diluted with measured quantities of distilled water until the opacity corresponded to that of the standard The amount of the dried bacteria in the standard could thus be readily calculated Conversely, it became easy to calculate the amount of the dry micro-organism in an unknown suspension by diluting to the opacity of the standard

The apparatus used consists of a Lummer-Brodhun photometer head to which two light-proof arms are attached, in each of which a small electric lamp can be moved back and forth by means of a screw After the light on the two sides has been equalized the standard test bottle is placed between the photometer and the lamp on one side and on the other side a measured quantity of the bacterial suspension to be determined in a tested bottle. This is then diluted with distilled water until the light which passes through both sides is the same. When this is the case, the suspension contains the amount of dry micro-organism represented by the standard All of the bottles used must be first tested optically when filled with distilled water The standard is made by using a suspension of electrosilicon in distilled water, which is allowed to stand a few hours to permit the heavier particles to sink. The fine suspension is then standardized optically with a suspension of the micro-organism equivalent to the desired amount of dried bacteria

In standardizing the pneumococcus, suspensions were used of washed living pneumococci of the types Rockefeller 1, 2 and 3, cultures of which had been kindly sent by the Rocke-

Pneumococcus Rockefeller 1

18 6071 dried at 110 C gave 0 0579
17 7126 dried at 110 C gave 0 0552
1 0 contains 0 00332 dry
1 1223 suspension diluted to 80 c c corresponds optically to standard
0 8844 suspension diluted to 64 c c corresponds optically to standard
Hence, 1,000 c c standard corresponds to 46 mg dry

Pneumococcus Rockefeller 2

19 3252 dried at 110 C gave 0 0512 dry
18 8286 dried at 110 C gave 0 0490 dry
1 0 contains 0 0026 dry
1 0427 suspension diluted to 60 c c corresponds optically to standard
0 9498 suspension diluted to 58 c c corresponds optically to standard
Hence 1,000 c c standard corresponds to 45 mg dry

Pneumococcus Rockefeller 3

18 2440 dried at 110 C gave 0 0488 dry
18 3318 dried at 110 C gave 0 0491 dry
1 0 contains 0 0027 dry
0 9460 suspension diluted to 60 c c corresponds optically to standard
1 1075 suspension diluted to 70 c c corresponds optically to standard
Hence 1,000 c c standard corresponds to 45 mg dry

In the preparation of the pneumococcic extract a suspension of living washed pneumococci was taken such that it corresponded optically to 1 8 gm dry to 1,000 c c This was heated to 38 C and an equal quantity of a solution of 0 2 per cent Cudahy Pancreatin and 2 per cent sodium bicarbonate also heated to 38 C was added The mixture was allowed to stand at 38 C for fifteen minutes and then barely acidulated with pure hydrochloric acid until the development of gas on the addition of acid ceased It was then filtered through a Pasteur filter which made it germ free and sterile When it was to be employed as an *antigen* it was simply put into small sterile bottles and kept in an ice chest For experimental and therapeutic purposes 0 1 per cent tricresol was added in order that it might be handled without fear of infection The tricresol was used only after it had been determined by experiments on rabbits that absolutely no interference with the immunizing properties of the extract was thereby produced

The effect of the action of the alkaline pancreatin on the pneumococci was absolutely inappreciable, for although immunizing substance was extracted, as will be shown in a later communication, the staining properties, the viability in culture and the virulence of the pneumococci were unchanged It was repeatedly proved that pneumococci so treated killed rabbits injected with them just as the untreated pneumococci did They could be grown from the heart's blood of the animals that died in exactly the same manner

Extracts of the gonococcus, streptococci, staphylococci, *Streptodiplococci rheumaticus* (Poynton-Payne), streptodiplococci of endocarditis and similar cocci were made in the same manner

With the members of the typhoid group like typhoid, colon hog cholera, it was found that although some results were obtained by extracts that had been subjected to the digestive process for fifteen minutes, better were given by such as had been acted on for thirty minutes, whereas longer periods gave less potent extracts Hence for this type of micro-organism thirty minutes was the period used as a routine

With tubercle extract the method employed was somewhat different, although the principle involved was the same After the germs had grown they were strained through cheese-cloth and thoroughly washed with distilled water The mass was partially dried with filter paper A weighed portion was dried at 110 C and a portion of the moist living bacilli, corresponding to 2 gm dry, was mixed with 500 c c distilled water heated to 38 C To this 500 c c 0 4 per cent Cudahy pepsin in 0 6 per cent HCl heated to 38 C was added and the mixture allowed to stand at 38 C. for three hours It was then made faintly alkaline to phenolphthalein with sodium carbonate and filtered through a Pasteur filter For use as an antigen the germ-free sterile fluid was simply bottled, whereas for experimental and therapeutic use 0 1 per cent. tricresol was added When correctly prepared, 20 c.c should kill a highly tuberculous guinea-pig weighing 250 gm within twenty-four hours, with a reaction consisting of hemorrhages in and about the tuberculous deposits, 15 c c. should not kill the animal, but should produce the reaction, which can be found by killing the animal and making a postmortem examination

This tubercle extract is entirely different from tuberculin in its qualities It is destroyed by heating to 100 C., which is not the case with tuberculin In making the extract it was found that digesting for three hours gave a more potent extract than when the ferment acted for a shorter or a longer period

Work is being done with numerous other micro-organisms, including the *Spirochaeta pallida* as there is every reason to believe that the principle of extracting the end-body unchanged applies to all bacteria

All of the ferments of digestion will act but for different types some seem better than others although it is probable that special methods could be worked out with each which would give as good results as any of the others

In the preparation of the various antigens accurate standardization of the micro-organisms is not necessary Any moderately thick suspension may be used and an equal volume of the solution of the digestive ferment added according to the method described above Of course, it is necessary in each case to determine the antigen value just as is done in making the ordinary Wassermann test.

With the discovery of the principle of complement fixation of the bacterial antibodies by Bordet, the possibilities of diagnosis entered on a new era The investigations on the subject that have been made since then have fully confirmed the correctness of Bordet's conclusions Practical results of great value have been achieved with the gonococcus, mainly through the work of McNeal and Strauss With the other micro-organisms, however, the diagnostic value of the method has not met with general acceptance, as the results have been rather variable It has seemed probable that this has been due to the difficulty of obtaining a good antigen and not to any incorrectness of the fundamental principle As investigation with extracts of numerous micro-organisms made with digestive ferments and with the bacteria after extraction indicated that the substance extracted was not an autolyzed product but the real end-body, it was

thought probable that the extract would be an efficient antigen The tests thus far made have warranted this opinion As the antigens are very easily and rapidly made in any laboratory, it is to be hoped that further trial will be made by others

The following results shown in the tables in complement fixation with the various antigens prepared by the action of the digestive ferments on washed living bacteria according to the method described, were obtained by Dr Edward Johnson and Mr George Gillnan of the Pacific Wassermann Laboratory Great credit is due them for the careful manner in which they observed all the precautions and used all the ordinary controls employed in the Wassermann tests

one-half hour, and gave positive results It was tested on one case of pneumonia only just before the crisis and gave + + + fixation The antigenic unit was 0 1 c c

RHEUMATISM

A small number of cases of rheumatism were investigated serologically with extracts of various micro-organisms The extract of the Poynton and Payne *Streptodiplococcus rheumaticus* was made from a single strain Its antigen unit was 0 3 c c The extract of the streptococcus of endocarditis was also made from a single strain Its antigenic unit was 0.2 On testing with the extract of another strain of the same

AN AMEBA IN SUPPURATIVE AND HYPERPLASTIC OSTEOPERIOSTITIS OF INFERIOR MAXILLA *

KENNETH M LYNCH, MD
CHARLESTON, S C

In 1896 Flexner[1] reported an ameba found in artificially obtained pus from an abscess on the floor of the oral cavity Doflein,[2] in 1901, observed a similar ameba in an abscess with fistulas opening on the right lower jaw The latter case resembled, somewhat, the following, although there are certain differences in the two parasites observed

History—E W, a negro woman aged 23 servant admitted to the Roper Hospital in Charleston, April 20 1915 beginning about one year before had frequent attacks of toothache The lower jaw on the left side began to swell about a month previous to admission when she exhibited a hard nonmovable tumor the size of a hen's egg attached to the inferior maxilla Nothing abnormal was noted in the mouth or throat. The cervical lymph nodes were palpable The temperature, normal in the morning went up to 99 and 100 in the evening

A diagnosis of osteosarcoma was made and the left half of the mandible resected and sent to my laboratory

Examination of Specimen—From articulation to canine tooth the bone was thick with rough surface into which ran small clean-cut sinuses containing thick white granular pus The thickening was most prominent about the middle of the body of the bone where it was of tumorous appearance. Over this prominent portion on the outside was a hard fibrous mass attached to the bone and to the surrounding muscles In this were several larger sinuses leading into the bone Saw cut revealed the bone to be of a compact cancellous nature, like new growing bone honeycombed with small pus sinuses The first molar tooth was missing and the third was represented by a decayed root, level with the soft tissues of the gum.

Microscopically the composition of the tumor mass was of newly formed and forming bone trabeculae fibrous tissue, mainly old, encroaching on surrounding muscle lymphocytic infiltration, largely in localized foci and small areas of necrosis and pus in which were rounded hyaline nonnucleated bodies somewhat larger than leukocytes The appearance was that of inflammatory overgrowth of bone and connective tissue of a progressive nature showing areas of necrosis and pus formation corresponding to the previously mentioned sinuses

Microscopic examination of the pus revealed no recognizable bacteria, nor did animal inoculation give any results It contained in addition to granular materials, neutrophilic leukocytes and a goodly number of eosinophils some recognizable tissue cells and numerous ameboid cells These when rounded were about 40 microns in diameter, with a distinct clear ectoplasm and coarsely granular endoplasm of refractile bodies No nucleus was recognizable. These cells were ameboid throwing out, slowly large broad single pseudopodia which were seen to engulf red blood cells and leukocytes The cell moved from place to place by projecting one of these pseudopods into which the endoplasm flowed, it then becoming the body

Stained with Leishman's fluid the cytoplasm was very faint vacuolated, and contained red blood cells and fragments of leukocytes No nucleus was observed Unfortunately, these specimens were destroyed before I had completed my study of them or had opportunity to use other stains

That this ameba was not of those commonly found in the mouth was plain to me because of its size, activity, character of endoplasm, and staining properties It differed from Doflein's parasite in that it was sluggish in action and exhibited single large blunt pseudopodia and a distinct differentiation of ectoplasm from endoplasm, while the latter was more active than those of amebic dysentery and developed long fingerlike pseudopodia of apparently the same appearance as the protoplasm in general

Doflein conjectures that both his and Flexner's parasites were dysenteric amebas, although there was no history of dysentery in either case Neither was there history of dysentery in the present instance, and the variance in morphology of the ameba connected with the history disputes such an opinion in this case

That the ameba was the etiologic factor here cannot, of course, be said, but the absence of any other recognizable factor, the nature of the growth, the history of onset and the decayed tooth as a possible port of entry, lend the suggestion

THE SUGAR CONTENT OF THE BLOOD IN CERTAIN DISEASES OF THE SKIN

A PRELIMINARY REPORT *

I R PELS, MD
BALTIMORE

Since it is well known that diseases of the skin, such as furunculosis, occurring in various areas of skin are associated at times with a transient or even a permanent glucosuria, as in diabetes mellitus, and since it is known also that a hyperglycemia may be present, under certain conditions even in the absence of a glucosuria, it occurred to me that it might be of interest to make investigations along these lines in certain dermatoses

It was intended to ascertain, if possible, any changes from the normal, in those conditions in which the cause, or underlying etiologic factor, was more or less unknown The tests, therefore, were made merely to answer the question whether there was an increase or a decrease in the sugar content of the blood, compared with the normal

The cases were selected at random, but in practically all it could be assumed that there might be some disturbance in metabolism or some systemic disorder The patients were selected from both sexes at the outpatient service of the Johns Hopkins Hospital, and nearly all were white adults The blood was obtained, invariably from a vein in the forearm, approximately from one to three hours after the last meal eaten This probably had some influence on the degree of glucose percentage The urine was examined in every instance The specimens were obtained after the venipuncture, and were examined at once for albumin by the heat and acid test, and for glucose by the copper sulphate-alkaline test (Fehling)

The method employed was a modification of the Benedict-Lewis procedure, as proposed by Epstein,[1] and carried out by specially designed apparatus This method was found to be satisfactory because of its convenience, simplicity, and rapidity of execution It was tested against the original Benedict-Lewis method

[1] Epstein A. A An Accurate Microchemical Method of Estimating Sugar in the Blood, The Journal A M A. Nov 7 1914 p 1667

Aside from the two cases mentioned, we had no disagreeable complications, except those mentioned above and observed by everybody else They evidently constitute the regular clinical picture following the neosalvarsan injections, being, as it were, a clinical reaction to the latter They are pointed out by Swift, who says that a given dose may be well tolerated several times, but later may be followed by severe symptoms He recommends, therefore, extreme caution in the injections and a dose not exceeding 0 5 mg With such a small dose, Swift obtained in three patients out of thirty-four (the rest usually received intravenous and intraspinal injections together) quite encouraging results from the biologic standpoint (favorable changes in the cerebrospinal fluid) About clinical changes, Swift says only that he was "struck with many instances of parallelism between condition of the spinal fluid and general condition of the patient"

Giving intraspinal injections of neosalvarsan, I was interested not so much in the possible biologic changes of the spinal fluid as in clinical changes, which unfortunately were *not very favorable, in spite of the large and repeated doses* The results, I must confess, were in the majority of cases much better from internal administration of plain arsenic, of arsenic trioxid, given in large doses according to a method used in the treatment of chorea and described by me some time ago[6]

I have been using this method in my private and dispensary patients in the form of a 1 1,000 solution of arsenic trioxid (arsenic trioxid, 0 12, diluted hydrochloric acid, enough to dissolve, distilled water, 120 0), which is given once a day, after a meal, beginning with half a teaspoonful well diluted with water During the following days the dose is each time increased by a half a teaspoonful until 6 or 7 teaspoonfuls are given to one dose (always well diluted with water), after which the dose is daily decreased by one half teaspoonful until the initial dose of one half teaspoonful is reached If no changes in the patient's state are noticed, or no complications of the stomach (vomiting) or the urine (albumin) are present, the arsenic treatment is renewed in ascending doses until three or four or more courses are given

That arsenic given internally may reach the nervous system is proved by a case of Comby,[7] whose patient, a 7-year-old girl, took in eleven days 4 grams of arsenic, and developed a myelitis (paraplegia, incontinence of bladder and rectum, etc), of which the child recovered within three weeks This method is practically devoid of any danger, as I never met any serious complications in spite of the fact that it was used in small children Of late, I began to use the same method also on my county hospital patients instead of neosalvarsan injections, and had in many cases results not worse if not better than from neosalvarsan therapy

School Medical Examination—The Supreme Court of South Dakota has decided that a regulation of the school authorities of Aberdeen requiring that each child seeking admission to the schools must furnish a "physical record card" signed by a physician, was reasonable and valid, that it did not unlawfully bar any pupil from the schools, and that the school board had authority to adopt such a regulation —*Public Health Reports*

VACCINE TREATMENT OF GONORRHEA*

CARL C WARDEN, MD
ANN ARBOR, MICH

In a recent paper[1] I reported experiments on the gonococcus from which the following observations were made

Autolysis is an invariable character of the gonococcus in the presence of excess of water, and is due probably not to enzyme activity, but to water hydrolysis and solution By autolysis, I mean the solution or disappearance of the cocci which always occurs in the presence of excess of water, whether the water be in the culture medium, in the menstruum used for the preparation of a vaccine, or in the tissues of animals

The process of autolysis, which is favored by the delicacy of the limiting surface and by the easy vulnerability of the coccus and its ready permeability by water, consists in edema followed by liberation of protein, or protein split products, compounds containing phosphorus, and fats

The gonococcus protein, comprising 75 per cent of the entity of the organism, is liberated into the salt solution or water during autolysis, and at first exists in chemical forms representing the sum of metabolic activity at the moment of liberation, but which undergoes fairly rapid changes in character, either by water hydrolysis, by the action of ferments not killed by high temperature, or by other agencies, so that in a short time the organic nitrogen has largely lost its identity as gonococcus protein and has assumed simpler chemical form

The fats of the gonococcus, obtained as fatty acids, neutral fats and lipoids, are of large bulk, and a considerable proportion of the former are volatile and soluble in water and salt solution

Suspensions of gonococci in water or in salt solution, as in the preparation of antigen and vaccines, undergo rapid, almost immediate, autolysis, accompanied by the changes above mentioned, at all temperatures below the coagulation point of protein Heating at 60 hastens the process, while 70 coagulates the proteins

Fresh suspensions or autolysates are fatal to guinea-pigs The toxicity declines rapidly to a fairly constant level, then ultimately disappears The toxicity appears to be associated in measure with the *character* of the nitrogen rather than with the quantity

I have shown that fresh, live gonococcus culture suspended in water or salt solution and injected intravenously or otherwise into laboratory animals shows a toxicity almost inversely proportional to the length of time the cocci have been in suspension, being greatest within the first few minutes, diminishing rapidly by hours and days, and finally disappearing altogether During this time the gonococci show, microscopically, progressive disintegration, swift at first, then more deliberate, until finally there are no cocci to be found As I have shown, heat and chemicals may modify or check these changes, but only by damage to the cocci in other ways Freshly prepared gonococcus vaccines are therefore toxic, while aged vaccines are inert

Autolysis of whole gonococcus also occurs on wet culture mediums, in serum, normal, immune and mactreated, in all electrolytic solutions in which cell permeability is increased, and in all cavities and tissues of laboratory animals Autolysis is prevented by alcohol, by electrolytic solutions of high ionic content, by fatty substances, by soaps and by hygroscopic nonelectrolytes, such as glycerin and syrup

---

* Read before the Section on Genito Urinary Diseases at the Sixty Sixth Annual Session of the American Medical Association, San Francisco, June 1915

[1] Warden, Carl C *Jour Infect Dis*, May, 1915

The viability of the gonococcus may be maintained for days in glycerin, lanolin, and cold cream, at room temperature I believe such anhydrous substances to be frequently responsible for the dissemination of gonococcus infections

It will be observed that gonococcus suspensions in water or salt solution are not unlike sterile autolysates of other cells, and consist of substances much changed from their former character in the living cocci A question of importance is to what extent such suspensions may be expected to create active immunity in animals I know of no way by which whole unautolyzed or live cocci may be introduced into an animal except by suspending them in glycerin, fats or neutral oils, or by transferring fresh culture material directly to the tissues By all methods lysis occurs in the animal in the same manner as in water or serum in vitro Animals immunized with gonococcus suspensions in water or salt solution and with autolysates yield serum containing quite variable amounts of agglutinin, no definite germicidal substance, and irregular opsonic power The immune serum fixes complement with gonococcus antigen, which is merely gonococcus autolysate It is probable that the lysis following the introduction of live, unautolyzed gonococci into laboratory animals is of the same nature as that occurring in serum in vitro Numerous observations on intraperitoneal lysis have shown that the primary products of dissolution act as aggressins The cocci quickly enter the circulation and are found in the liver and spleen in all stages of lysis, but rarely within the leukocytes It is probable that the immunity response to gonococci in animals gives true gonococcus antibodies only in part, the remainder, if any, being antibodies to products of lysis In speculating on the role of gonococcus nitrogen in the body, a question rises whether the administration of vaccines in gonorrhea may not produce antibodies to the products of autolysis in large measure, and to true gonococcus antibodies in less It is doubtful whether vaccine (autolysate) given to man and other animals occasionally produces substances in the serum which fix complement with gonococcus antigen (autolysate) By this I mean that the administration of vaccine to a normal individual or to one suffering from gonorrhea, does not of itself bring about a positive complement-fixation test with the serum of that individual Fixation of complement with the serum of individuals with gonorrhea does not occur until a stage of the disease is reached, the sixth to the eighth week, when probably lysis of the cocci in the tissues has begun or is increased Such an assumption is certainly admissible, from the foregoing evidence

Now, if the immunity response to vaccines is directed more against the products of lysis than against true gonococcus antigen, it is not unlikely that such antibodies may merely neutralize the products of lysis occurring from cocci at the site of disease[2]

Not all vaccines are prepared in the same manner, but there are objections to all Washed cocci have undergone extensive lysis with consequent liberation of fats and nitrogen, as I have shown by chemical examinations of the wash water Repeated washing occasions further loss until nothing but granular material remains It can readily be seen that the standardization of gonococcus vaccine by the method of counting is impossible save when the cocci have been altered, or fixed, by heat or chemicals Suspensions heated to 60 show autolysis hastened, and 70 coagulates the proteins[3]

In sensitized vaccines the cocci have yielded products to the serum, and there is no evidence to show that they have gained antibody from the serum Such vaccines are merely gonococcus residue Abundant evidence has shown me also that unautolyzed vaccine is toxic and only slightly greater in antigenic value than ordinary vaccine My studies on autolysis led me at one time to believe that if a vaccine of whole, unautolyzed, unchanged gonococci could be produced, better results would be obtained in the treatment of gonorrhea by such a vaccine Accordingly, I learned first how to cultivate the gonococcus free from autolysis, and later how to preserve the whole cocci in anhydrous menstruums Vaccines were made of quickly dried gonococcus substance suspended in neutral oil, others of fresh unautolyzed cocci in pure glycerin and in neutral oil, and all were thoroughly tested out on animals and patients In all cases, the results were the same, all were toxic, the glycerin vaccine more so than the oil, and appeared to have no effect whatever on the course of the disease On the other hand it was plainly shown that whole, unautolyzed cocci, alive or killed, underwent autolysis when introduced into the tissues of the body exactly in the same manner as in fluids in the test tube, followed by toxic manifestations, local or general, slow or rapid, according to whether the menstruum employed was oil or glycerin

The beneficial results following vaccines in gonorrheal rheumatism, for which there is some evidence, might appear to be contradictory to the ideas above expressed, were it not possible to explain them on the same hypothesis Not infrequently, especially with freshly prepared vaccines, it has been noticed that the reactions following their administration to patients include pain in the joints In animals inoculated with water suspensions I have noticed stiffness and apparent tenderness of joints, although no gross changes could be found Serum from patients with gonorrheal rheumatism gives the largest proportion of complement fixation The serum of goats immunized with fresh gonococcus suspensions in salt solution gives a precipitin response with gonococcus autolysates, fresh and heated to 75 This evidence, though inconclusive, nevertheless suggests that conditions about the joints may be more favorable to lysis of the cocci than in the tissues of the urethra, and that the products of lysis may contribute to the symptoms The relief of pain following gonococcus vaccines is one of the most conspicuous results Without carrying the argument further, the same explanation may suffice for other complications of gonorrhea, including salpingitis

From the evidence submitted, it is assumed that the character of autolysis in the gonococcus renders immunity response of animals and man to injections of the organism unsatisfactory and incomplete In other words, the organic nitrogen of the gonococcus does not seem to be altogether available as antigen This assumption is strengthened by the fact that the nitrogenous portion alone of watery antigen made by me for complement fixation is much poorer in antigenic power than the whole autolysate It was necessary, then, to search for some substance other than protein, or its split products in the autolysate or watery antigen which, with immune serum, would fix complement These substances were found to be the fats of the gonococcus, since these substances, chemically isolated from the organism, and suspended in absolute alcohol, possess a much higher antigenic power than the watery antigens of commerce

---

[2] A matter of common observation has been that autolysates were distinctly inhibitory to growth of the gonococcus and should conditions be at all comparable within the body and in artificial culture it may be seen that such antibodies might not be incompatible with the continued existence of gonococci in the tissues.

[3] Zinnser Effects of Heat on Antigen in Precipitins and Agglutinins Infection and Resistance, 1914

The question of whether there may exist with these fats an inseparable and essential nitrogen *"rest"* need not concern us at the present time

I submit a report, preliminary to a forthcoming paper on the subject by L E Schmidt and myself, on complement-fixation tests in which the best of the commercial antigens and my own were used parallel Up to the present, 279 tests have been made and the results show indisputably the importance of the fats in the reaction The serums of 50 normal individuals gave no fixation, nor did the serums of 47 persons with diseases other than gonorrhea

In acute cases under one month, the commercial antigen gave positive tests in 20 per cent, the lipoid antigen in 50 per cent

In subacute cases, up to six months, commercial antigen in 20 per cent, lipoid in 75 per cent

In cases of long standing with repeated or recurring attacks, commercial in 33 per cent, lipoid in 65 per cent

In past cases—over six months to thirty years—of doubtful character, commercial in 16 per cent, lipoid in 50 per cent

In children, all stages included, commercial in 10 per cent, lipoid in 66 per cent

With my lipoid antigen, complement fixation appears at an earlier period, occurs with greater regularity during the disease, and endures longer than with commercial antigen All watery antigens are likely to show periods of alternating positive and negative reactions during an attack of gonorrhea, in which the administration of vaccine takes no[4] part The lipoid antigen shows less fluctuation of this character

The facts shown in this preliminary report appeared to me to place these fatty substances in an important light from an immunologic view,[5] and I have sought to test their antigenic power as a therapeutic agent in the treatment of gonorrhea This was specially desirable because of the unsatisfactory results in the use of autolyzed and whole, unautolyzed, gonococcus vaccine It was found that the fatty moiety is nontoxic for normal man and other animals, even when given intravenously in large doses

The results, briefly summarized, of the treatment of gonorrhea with gonococcus fats are to be regarded as tentative, and constitute a preliminary communication on the subject

The cases treated by me thus far comprise acute, chronic, simple and complicated, in men and infant girls In all, the subcutaneous inoculation of the fats has been followed by marked improvement, and in some by unodubted cure

The chronic cases, in which there are posterior involvement, with slight but constant discharge containing gonococci in smear and culture, have shown disappearance of cocci in discharge, and symptoms, following one to three inoculations The acute cases, taken within the first forty-eight hours of the discharge, showed complete disappearance of gonococci in smears and cultures, and entire absence of the discharge within a week following *one* inoculation Between these extremes are those acute cases showing well-established infection, copious discharge, and considerable edema, which have required more frequent inoculations with increasing doses, and which constitute an improved, but unfinished series, owing to lack of material

There has been a slight local reaction, consisting in reddening and swelling of the subcutaneous tissues, which quickly subsided In some instances a constitutional reaction characterized by chilly sensations, anorexia and some fever appeared in from six to eight hours This reaction has not been constant, but is followed by marked clinical improvement The first indication of improvement is the diminution in the number of cocci in the exudate, which in some cases constituted a striking sign The coincidence of the disappearance of cocci and the constitutional reaction, together with my experience with anaphylactic reactions in animals following the administration of fresh gonococcus autolysates, or following lysis of whole cocci in vivo, has led me tentatively to infer that the reaction in question may be due to the sudden lysis of the cocci in the body of the patient

1310 Hill Street

ABSTRACT OF DISCUSSION

Dr J A. Fulton, *Astoria, Ore* I have done no work in this line I believe, however, that when one in the profession finds that which he thinks is of consequence it is his duty to present it Owing to the low vitality of the gonococci, acute gonorrhea should be easily checked with injections, were it not for the fact that by the time the disease manifests itself the bacteria have buried beneath the epithelium, where they are protected

The urethra will stand a temperature of 120 Fahrenheit without injury I have demonstrated that with a bougie heated to 120 F in the urethra, a thermometer placed alongside of the urethra with the skin folded over it, a temperature of from 104 to 106 was shown, indicating that heat penetrated living tissues and raised the temperature of the skin from 5 to 7 degrees, and showing that even if the bacteria do bury under the epithelium, the heat surely reaches them

Heat must be used carefully and accurately One degree difference in temperature may make for either success or failure, just as one more grain of a drug in solution may determine whether your patient is cured or killed This I wish to impress on every one who attempts the use of heat for the cure of disease The method followed in making applications of heat to the urethra is this the bougie is so constructed as to allow the circulation of water from one end to the other At the entrance and exit of this circulating water is placed an ordinary pair of irrigating thermometers so arranged as to show the temperature of water as it enters the bougie and also at the point of exit, so one may know always the exact temperature of the bougie within the urethra The water is heated in any convenient way, but is kept at such a temperature all the time, so as to show 120 F at point of entrance The urethra is washed out with warm boric solution, and with the patient in a recumbent position the bougie is introduced down to the cut off muscle, and the heat is turned on. The application should last for at least thirty minutes. The temperature of the bougie should not be allowed to vary. It should always show 120 or within a fraction of that point. After this application, the mucosa where touched by the bougie is slightly swollen, and there is some discomfort on urination. The discharge changes to a watery mucoserous character and disappears in from ten to fourteen days as a rule.

---

[5] Meyer, Kurt Antigenic Nature of Lipoids, Ztschr f Immunitäts forsch u exper Therap, xix, 20

My experience convinces me that almost every case of acute gonorrhea, that is, cases in which the disease has not gone into the deep urethra, may be aborted, and many cases of chronic disease cured, through the proper application of heat.

Dr. Frank Hinman, San Francisco: The paper would seem to have two practical lines of application: in the first place in treatment and in the second place in diagnosis. The subject of immunization is a very complex one. There are two principal forms, active and passive immunization. In passive immunization the specific serum that has been produced by active immunization of animals is injected and exerts directly its antitoxic powers. Such passive immunization is possible for those organisms only which secrete a soluble toxin, such as diphtheria, tetanus, etc. Passive immunization cannot be produced with gonococci, for the reason that the gonococcus secretes no toxin but produces injury, possibly after death or autolysis. The immunity of diphtheria is an antitoxic immunity, whereas immunity in the same sense is never established against the gonococcus, but is bactericidal through the interaction of immune substances and complement. Active immunization of the bactericidal form has been shown to be of practical value particularly for typhoid prophylaxis and more recently by using Gay's sensitized vaccine for acute typhoid, for furunculosis, etc. The failure of gonococcus vaccine as an active immunizer and of the gonococcus antigen as a deviator of complement as usually used, has been beautifully explained in this paper of Dr. Warden. The action of the gonococcus is evidently twofold, by injury from substances of autolysis, and by injury from the true gonococcal amboceptor. The fatty and lipoid extracts according to Dr. Warden are nontoxic, but antigens and vaccines made of these lipoids and fats are much more active than the autolysates. These lipoid substances may have the same side-chain grouping as the true gonococcal amboceptor, since they are so much more active than the autolysates, and would be, in a way, analogous to the toxoids in diphtheria immunity. Now, if by the use of these lipoids we can get the gonococcus in a nontoxic but specific form, we will then be in a position more correctly to diagnose gonorrhea and to use vaccines satisfactorily in the treatment of acute gonorrhea and gonorrheal complications.

Dr. John Campbell Spencer, San Francisco: Dr. Warden's contribution practically relegates to the scrap heap all products of the views regarding vaccines and watery suspensions with which the market is drugged at the present time. It is an eloquent treatise on the relative inefficiency of our therapeutic attempts at the present time to treat gonorrheal infection by vaccines. Personally I am glad that I have been present to listen to Dr. Warden's elucidation of this subject because it looks as though we were entering on a new epoch in our treatment of gonorrheal infection. It will be of great benefit in the elimination of this scourge of the human race.

Dr. Louis E. Schmidt, Chicago: I have been fortunate enough to be with Dr. Warden in his laboratory work and to supply much of his clinical material. The purely scientific part of the article I do not wish to discuss, but it seems to me to be the most thorough explanatory article on this subject. It seems to set forth very clearly, at least to me, the reason why we have had so many failures in clinical treatment of patients, and the failures of the gonorrheal complement tests are accounted for. We know that there are any number of instances in which the test has not given us a satisfactory answer. It has always been rather surprising that where we have been able to find gonococcus in culture and in smears, the test has frequently been negative. This holds true in connection with the work in children. The explanation given here clears up the question perfectly to me and gives us a basis for an answer regarding our failures.

Regarding the ordinary vaccine treatment of gonorrhea and its complications, it has practically been relegated to the background. It has been attended with few satisfactory results. Dr. Warden in this paper states that with the old vaccines there have been a limited number of cases in which the results are satisfactory. Certainly the vaccine treatment of gonorrhea, and its complications, is not as satisfactory as the vaccine treatment in certain other conditions. The explanations he has given certainly help to clear up the subject. The vaccines that are on the market at the present time do not adhere to any theories that Dr. Warden has laid down. How do they act? Certain results are gained by giving certain remedies without any known reason therefor. The answer always is, of course, that the results are satisfactory. It is far more satisfactory to all of us to follow the reasons why we get unsatisfactory as well as satisfactory clinical results.

The antigen of Warden is unquestionably far superior and gives more accurate results than the watery antigens on the market. As to treatment, the number of cases up to the present time is limited. However, they go into hundreds, and comparing the results with all other similar methods of treatment I can personally state that in this series of cases which I have had under my observation they are markedly different and more satisfactory.

Dr. Lewis Wine Bremerman, Chicago: If Dr. Warden has all that he claims, we have made a definite advance in the therapeutics of gonorrheal infection. We all have used commercial vaccines and discarded them, using the antigens which were manufactured, and discarding them because we did not get the proper results. Gonorrheal complications and the sequelae constitute the majority of cases of the genito-urinary specialist. If we can advance along the line of treatment we are doing something that will be for the benefit of a large number of people, as well as to the medical profession. I hope and trust that he has an antigen that will give all of the good results he claims for it, because I have worked along this line myself in my own laboratory with commercial antigens with very unsatisfactory results. I cannot see why the complement fixation tests for gonorrhea cannot be made as satisfactory as the complement fixation test for syphilis. If we can prove up the complement fixation equally with syphilis we are advancing an excellent method of diagnosis.

Dr. Fred R. Charlton, Indianapolis: I am glad to add my word of gratitude to Dr. Warden for what he has done. I have been one of the discouraged ones, having used the various products seriatim, as they have been offered, without any clearly defined good results whatever. If the treatment that Dr. Warden outlines here proves satisfactory I am going to feel a little more sanguine as to the general procedure. Such work as his again shows the folly of plunging the profession into "fads" before they are studied. Vaccinotherapy has been nothing less than a craze heretofore. Perhaps some benefit may yet be derived from a Neisser bacterin. To date I have seen none.

Dr. Granville MacGowan, Los Angeles: There is no disease civilized man suffers from that causes half the misery that gonorrhea does. Anything that serves to make it more rare, or make it more readily curable, and to relieve the troubles which come from it is a boon to mankind.

The thing that impressed me most in this admirable paper was the significance of the keeping alive of the gonococci by fats and greases. I think that the usual advice to men is to anoint themselves well with fats before coming in sexual contact with their female companions, and then to wash themselves thoroughly afterwards. One can very readily see how if a free use of fat is made by the male or female, and it is not thoroughly removed immediately after the sexual congress that if one or the other of the participants has gonorrhea the other is pretty sure to have this disease within a few days after the congress The second point brought out shows why we have all failed so markedly to cure or relieve gonorrhea with vaccines

Dr Carl C Warden, Ann Arbor, Mich There are two points that I think need emphasizing One is in regard to the presence or absence of protein or nitrogen in these lipoids We cannot absolutely say that nitrogen is wholly excluded from this product, no matter how perfect our chemicals may be I may say that this nitrogen, if it exists, is one of the essential parts, coupled with the fats

In regard to the complement fixation, it seems very strange that we do not obtain a complement fixation test at all times during the course of gonorrhea The question arises why do we not, especially in the florid stages of gonorrhea, obtain a higher percentage of complement fixation test than we do We shall always be embarrassed by this fact I think the reason for it is fairly evident Man is almost wholly immune to gonococcus to begin with There are very few tissues left in the body on which the gonococcus is able to exist. The blood stream occasionally shows gonococcus infection but these cases are extremely rare Now, then, those positions in the body that are subject to gonococcus infection happen to be extremely remote from the great laboratory of antibody formation, and for this reason it is a long time before the fluids of the body are enabled to form antibodies against the coccus It is only when the disease is beginning to get pretty well along, in from the fourth to the eighth week, that complement fixation appears as a really established thing The greater the amount of antigen the coccus gives to the body as a whole, in the great laboratory of antibody production, the sooner we will find complement fixation positive When the deeper structures of the urethra become involved and the complications of gonorrhea appear, and when the general conditions become manifest, then is the time we have the largest per cent of complement fixation These conditions, I think, we shall always have to contend against, and we shall never be able to find antigen which will fix the complement under all conditions The old watery antigens act variously, according to their fatty contents A new arrangement of the fats and new lipoids will fix complement in the largest percentage of cases There is abundant work to be done on the subject

Dr Fred R Charlton, Indianapolis May I ask Dr Warden whether in his therapeutic experiments he has confined himself to autogenous or the heterogeneous?

Dr. Carl C Warden All strains of gonococcus I have used every one that could be obtained in the ordinary course of the examination of patients I have succeeded in getting together probably forty or fifty different strains The work of Torrey, and a good many others, has shown that if a dozen or more strains are employed, those strains will probably embrace all the variations I feel that by having a large number of strains I have covered all the different varieties that might occur I do not attach any particular significance to autogenous vaccines I think better results are obtained from using many strains than one

---

Experimental Vivisection and the Rights of Animals—I cannot argue with the man who insists that his dog and his hog are as good as he is, that he has no right to restrain the one or to eat the other If he refuses to eat meat, or eggs, drink milk, use leather, wool or other animal products for clothing or shelter, if he refuse to make counter attacks against the lions or serpents which attack him, he is consistent, I cannot argue with him, I can merely watch him go his way in the procession with the trilobite, the ichthyosaurus and the dodo But intensely practical questions arise and must be met And the life of a relatively few animals is placed against the life and health and comfort of the human race The antivivisectionist insists that even if you grant that the injury to the guinea-pig or the rabbit or the horse will save the life of a child, you have no right to save it in that way If there is not room in the life-boat for the woman and the dog you have no right to push out the dog to make room for the woman—Samuel S Maxwell, *Science*

PERFORATION OF THE BILIARY TRACT

REPORT OF TWO CASES

HOWARD L BEYE, MD
IOWA CITY, IOWA

Perforation of the biliary tract is so infrequent as to warrant the reporting of unusual cases In the following two cases of perforation of the gallbladder, the patients were operated on by Dr C J Rowan in the surgical clinic of the University of Iowa

Case 1—*History*—L E, schoolboy, aged 11 years, referred by Dr Sinning of Iowa City, on the afternoon of Sept. 7, 1914, while playing, received a blow in the abdomen from one of his playmates This caused him to faint, and after gaining consciousness he was in so much pain that he screamed and had to be carried home During the following night he complained of a great deal of pain, and was very restless The next morning he vomited profusely, and the pain became worse on the left side, and was more marked here than on the right The temperature ranged between 100 and 101 on this day The bowels refused to move even with enemas and after calomel There had been no chill.

The past history was negative, except that about two months before, the boy had received a blow in the abdomen, at which time he was sick for three days with a high fever and vomiting The bowels were moved with difficulty Following this he was apparently perfectly well until the present trouble

Examination—The patient was brought to the University Hospital at 8 30 p m, September 8 At this time the temperature was 100.8, pulse 100, and respirations 40 His face had a drawn, anxious look, and the respirations were rapid and shallow He preferred to be on his side with the thighs and knees flexed, and complained of pain in the abdomen when moved The walls of the abdomen were rigid, this was perhaps most marked in the right upper quadrant, though the patient complained mostly of pain in the left side There was dulness in the right upper quadrant No palpable masses No cough Heart and lungs negative Leukocyte count 21,300 A diagnosis of ruptured appendix and general peritonitis was made

Operation—Under ether anesthesia, a midline incision was made below the umbilicus There was properitoneal edema The abdomen contained a large amount of bile-stained fluid, and considerable fibrin in plaques The proximal half of the small intestines was distended, and the distal half collapsed The intestines were examined for perforation, and none found The incision was carried up to the right of the umbilicus to the gallbladder region The gallbladder was found to be thickened and adherent to the liver, and contained a single perforation in the fundus from which pure bile was pouring No stones were found A rubber tube drain was led down to the perforation, together with a cigaret drain and a strip of iodoform gauze A rubber tube drain was led from the pelvis at the lower end of the incision The usual closure was made

Course—The patient was placed in Fowler's position and given normal salt solution by rectum, and nothing per mouth Recovery was uneventful The patient left the hospital on the fifteenth day

The interesting point about this case aside from the perforation is the chronic cholecystitis present in a child of 11 years The relationship between the condition of the gallbladder and the injury received two months before the perforation is problematic At that time the patient might have had an acute cholecystitis which was followed by gallbladder changes which predisposed to later perforation, or he might at that time have had a perforation of the gallbladder with a localized peritonitis which resolved There is no his tory of typhoid fever, and there were no attacks of tonsillitis to account for the gallbladder infection

Case 2—*History*—Mrs M M, housewife, aged 57, referred by Dr A R Lynn of Marshalltown, for several years had occasional attacks of belching of gas, sometimes with vomiting independent of meals In February, 1913, she suddenly had a severe tearing pain under the right costal margin, radiating to the pit of the stomach Following this she vomited profusely for several hours The pain lasted an hour or more caused her to cry out in agony, and was finally relieved by a hypodermic. Four weeks following this attack she became jaundiced, and this condition persisted until the next fall In July 1913, she had a similar attack.

Ever since the first attack the right side has been tender, and a swelling gradually formed pointing in the right flank above the iliac crest. This finally approached the surface, the skin overlying became reddened and it was lanced An odorless fluid was obtained at first thin and yellow, and later thicker This gave her immediate relief from her constant ache and pain There has been a persistent discharge of a mucous secretion ever since, and recently she passed four wheat-sized calculi The general condition was good except for an increasing gnawing burning sensation in the epigastrium not referable to food taking

Examination—This was negative except for the abdomen In the right side between McBurney's point and the gallbladder region there was a palpable mass about the size of a small orange quite tender Leading down to this mass was a sinus from which a small amount of light yellow tenacious fluid was discharged.

Blood Hemoglobin 78 per cent (Sahli), leukocytes 9 300

Gastric Analysis Seventy-five c c in forty-five minutes. Total acidity 100 Free hydrochloric, 68 No blood

Urine Negative.

A diagnosis of mucous gallbladder fistula following perforation was made

Operation—Sept 28, 1914 under ether anesthesia, a right rectus incision was made above the level of the umbilicus The gallbladder was long and narrow, and was adherent slightly to the omentum, and at the fundus to the abdominal wall at the inner end of the fistulous tract. A large mulberry stone was impacted in the cystic duct. The gallbladder was excised from its connection to the abdominal wall, and cholecystectomy performed. Tube draining was carried to the stump of the cystic duct, and an iodoform gauze drain through the sinus

Course—This was uneventful except for the formation of a Hematoma in the operative wound, and the passage of a small calculus from the old fistulous tract, following which the latter healed The patient left the hospital Nov 3, 1914

One of the interesting points about this case was the very slight amount of adhesions around the gallbladder, considering the extent of the diseased condition which must have been present during the period preceding the discharge of the abscess through the abdominal wall

---

Measles—The essential points in regulations for the control of measles are The case shall be recognized and isolated at the earliest possible moment, the premises on which the case is isolated shall be placarded, the patient shall be isolated for at least five days after the appearance of the exanthem, adults and children who have previously had the disease need not be restricted, but it is advisable to warn them as to the slight possibility of second attacks, and keep them under observation, children who have not previously had measles and who are in contact with cases, need not be restricted for seven days after contact but should thereafter be isolated for at least ten days and carefully observed Disinfection after measles is useless and unnecessary Transmission of measles by third persons or fomites must be exceedingly rare, if it occurs at all—Harold Farnsworth Gray, *Jour Infect Dis*, November, 1915

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES"

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL

Ampuls Sodium Cacodylate Mulford 15 grains—Each ampule contains sodium cacodylate 1 Gm. (15 grains) Prepared by H K Mulford Co Philadelphia.

SOLUTION PITUITARY EXTRACT (See N N R., 1915, p 223) —The following dosage form has been accepted

Ampuls Solution Pituitary Extract Mulford 0 5 Cc—Each ampule contains solution pituitary extract 0 5 Cc. Prepared by H K Mulford Co Philadelphia

Therapeutics

TETANUS

The war has shown two very important facts concerning this infection 1 The germ is more or less universal in the regions of warfare 2 The results of its infection may be made negligible by the preventive use of tetanus antitoxin A brief review of this disease may be of interest

Hill[1] found that tetanus is more frequent in the tropics than in temperate climates, and that in the latter climates 86 per cent of all cases are traumatic in origin

The incubation period of acute tetanus is from one to ten days, and of subacute tetanus from ten to twenty days Fifty per cent of all cases develop between the sixth and ninth day, the majority apparently on the seventh day after infection Acute tetanus lasts from one to ten days, and subacute tetanus from ten to twenty days Not until the patient has lived until the tenth day of the disease is there an equal chance for life After the tenth day the patient's chances of recovery increase day by day

There is probably always more or less leukocytosis in tetanus, and Hill found the average count to be 13,000 The eosinophils seem to be diminished in number

The tetanus bacillus is a cylindric rod, larger at one end than the other, and is an anaerobic germ It is constantly present in the dirt of cities and on most country roads, as well as in barns and pastures Noble[2] has recently shown that this bacillus occurs in the intestines of otherwise normal animals, and he found the germ in the feces of eleven of sixty-one horses examined Further examination of these infected animals showed that the germ could disappear in a few weeks, but could also remain present as long as four months Such animals become tetanus carriers,[3] and are a constant menace to other animals which may receive injuries, and to their drivers and hostlers, who may have slight wounds on their hands These tetanus-carrying horses infect the dirt of the fields or streets on which they work or travel

The reason for the perpetual danger from the tetanus organism is that it will live, when not subjected to intense light or heat, for years The germ has also been found in the feces of cows, and has even been found in the feces of man[4] Animals obtain the bacillus from their food, probably principally from infected grass and hay When it is found in the feces of the human being, he has probably obtained it from eating contaminated uncooked vegetables

This bacillus gains entrance to the system almost always through a wound or abrasion, and, as has long been recognized, the most frequently infected wounds are contusions and crushing or lacerating wounds, especially those that occur from sliding, grinding and friction injuries in the streets and from lacerating wounds acquired in warfare, explosions, Fourth of July injuries, etc At first the infection is a local one, and it is stated that the bacilli do not often wander from the point of infection, but they soon produce their toxins, which cause the general disturbance

As this germ grows without air, it is evident, as urged by Muhsam,[5] that infection with other bacteria, pus germs, etc, which will use up the oxygen in the tissues, or in a more or less closed wound, will thus aid in the growth of the anaerobic tetanus bacillus Also, the destroyed tissues at the base or around the wound should be very carefully removed, as such structures, with their impaired circulation, instead of normally combating infection, promote it Muhsam also urges flushing suspected wounds with oxygen, perhaps well furnished by hydrogen peroxid solutions, as oxygen inhibits or stops the growth of the tetanus bacillus

The toxins of tetanus bacilli ascend the motor nerve sheaths and thus reach the spinal cord They unite with nervous tissue and seem to remain in a more or less fixed combination, hence the difficulty of the tetanus antitoxin combating the toxin that has become thus combined Prevention of tetanus by the use of antitoxin is easy, the cure of tetanus with antitoxin is difficult It is probably only late in the disease that the toxins circulate in the blood Sinigaglia[6] found the tetanus bacillus in the blood in a case of slow infection

The beginning symptoms of poisoning from this germ are aches and pains in the muscles, with a general lassitude, some headache, and soon some stiffness of the muscles of the back of the neck, face and jaw The wound or source of infection may show no change, in fact, may apparently be healed The more or less permanent contraction of some muscles and the convulsions of tetanus are too well understood to need description Spasm of the sphincters may make urination and defecation almost impossible The mind generally remains clear, unless there is very high temperature, which is one of the causes of death Death may occur during a convulsion from spasm of the diaphragm or spasm of the laryngeal muscles, or it may occur from exhaustion

It was for many years thought that tetanus antitoxin was of no great value when the disease was positively in evidence It was considered and taught that it was too late to expect any antitoxin activity Therefore, it is very encouraging, in the treatment of this disease, to note that Irons[7] has found in animal experimentation that antitetanic serum will save life when tetanus has already developed, and therefore should perhaps not infrequently save life in the human being If the patient cannot be treated before serious intoxication of the central nervous system has occurred, the toxins, Irons believes, may be neutralized by a large intravenous injection combined with an intraspinal injection of the antitoxin

Nicoll[8] has determined by animal experimentation in the Research Laboratory of the Department of Health of New York, in conjunction with Dr William H Park, and also by clinical experience, that from 3,000 to 5,000 units of antitoxin should be injected into the lumbar region of the spinal canal as soon as tetanus is diagnosed This injection should be done under an anesthetic, to inhibit any possible convulsion during the injection The volume of the fluid injected should be "brought up to 10 to 15 c c by the addition of sterile normal saline, the exact amount being regulated according to the age of the patient and the amount of spinal fluid withdrawn " At the same time he advises the injection of 10,000 units of antitoxin intravenously The spinal injection dose should be repeated in twenty-four hours, and a subcutaneous injection of 10 000 units should be given three or four days later Nicoll finds that the death rate has been reduced by this method of treatment of those who already show symptoms of tetanus

[7] Irons E E Tetanus and Antitetanic Serum The Journal A. M A, May 8, 1915, p 1552
[8] Nicoll Matthias Intraspinal Administration of Antitoxin in Tetanus The Journal A. M A June 12 1915 p 1982

These investigations, with the added clinical experience, would seem to make it doubtful if subcutaneous injection alone of antitetanic serum could cure tetanus, although Comby[9] states that he has cured three cases of tetanus in children by the subcutaneous injection of antitetanic serum

Subsequent injections of antitoxin, especially when given intravenously, can cause anaphylaxis, sometimes severe, and Simon[10] thinks that injections later than the tenth day become dangerous from the standpoint of being likely to produce anaphylactic shock

It has recently been shown[11] that if the tetanus antitoxin is injected into the tissues surrounding the wound soon after the injury, tetanus will be prevented, even if the tetanus bacillus is later recovered from the wound Teutschlaender[11] states that if, in such cases, a little stiffness or tendency to stiffening of the muscles of the part injured begins, he immediately gives another dose of antitoxin

The prophylactic dose of tetanus antitoxin should be about 1,500 units, given subcutaneously, preferably in or about the region of the injury, and this should be given whenever the character of the injury or the region in which the injury is received presents any possibility of tetanus infection This dose can be repeated in a few days if deemed advisable The serum may also be perfused into the open wound, but the antitoxin powder applied to the wound can probably not be relied on as an effective prophylactic An antitoxin impregnated pad is described by Robertson [12]

As in administering diphtheria antitoxin, it should be ascertained if the patient is susceptible to emanations from horses or stables, if he shows hay fever and asthma symptoms from such emanations, it is unwise to administer horse serum, especially as a prophylactic for something that may not occur

The newest of the drug treatments of tetanus is that by magnesium sulphate Solutions of this salt are injected into the spinal canal, and Eunike[13] injects 10 c c. of a 10 per cent solution This drug more or less successfully inhibits the convulsions If active symptoms recur in two or three days, he gives another dose of 8 c c of the 10 per cent solution Certainly the intraspinal injections of magnesium sulphate should be given only in very severe cases The dosage suggested by Eunike is not large, very much stronger solutions have been injected The danger lies in causing paralysis of the respiration Usener[14] states that subcutaneous injections of magnesium sulphate solutions are of value in relieving spasms and convulsions Cloetta[15] says that the action of magnesium sulphate is similar to the action of curare, perhaps not quite so dangerous, as its action may be inhibited by calcium Schütz has shown that magnesium sulphate diminishes heat production, and he thinks that the intensity of its action may be determined by the temperature curve [16]

Injections of magnesium sulphate into the system, and especially into the spinal canal, are always more or less dangerous, and it would seem that in serious convulsive conditions, while waiting for the antitoxin to have its effect, inhalations of chloroform would be safer in quieting and controlling the patient than injections of a substance whose activity passes beyond the control of the physician

Angerer[17] revives the chloral treatment of tetanus in conjunction with the antitetanic serum He gives as high as 5 grams of chloral by rectum twice a day, and adds to this one-sixth grain of morphin hypodermically By this means he gets a sort of "twilight sleep" He continues the antitetanic serum treatment, both intraspinally and subcutaneously, until the active symptoms of tetanus cease

While the dose of the chloral given by Angerer is very large, some such combination of morphin and chloral, with the dose gradually increased or diminished, depending on the symptoms, seems much safer than the magnesium sulphate treatment

Jacobsthal and Tamm[18] bathe all lacerated wounds with the ultraviolet rays, as they claim they will kill the tetanus bacilli as well as other bacteria Riehl[19] believes that he prevents tetanus infection of wounds by applying chlorinated lime in the form of a mixture of 1 part of the chlorinated lime to 9 parts of kaolin This powder is blown into and over all wounds This treatment, he reports, does not cause pain, allows the wounds to heal, and seems to prevent tetanus infection

Phenol treatment has been advised many times, and has been termed "Baccelli's treatment" Reynolds[20] reports the successful treatment of tetanus in a boy of 11 by phenol injections

Scallops as Food—The scallop industry in Massachusetts has recently increased greatly In 1906 the Massachusetts Fish and Game Commission at the instance of the General Court made an investigation and a report on the scallop industry, calling attention particularly to the sophistication of this food by soaking the scallops in water Inasmuch as the courts have decided that the practice of adding water to oysters is a violation of the law the Massachusetts authorities brought the matter of the possible violation of the law in regard to scallops to the attention of the federal authorities A joint investigation was then made, when it was disclosed that in some instances water in amount equal to the amount of scallops was added to the vessels in which the scallops were marketed Standards of purity were then advised by these authorities

Water in scallops may be detected by the fact that soaked scallops usually contain a milky fluid while unsoaked ones have almost no liquid. If a scallop is rubbed on the prism of an Abbe refractometer, and the refraction of the juice taken, unsoaked scallops will give a reading at 25 C. of 1 38 plus on the scale while soaked ones give a reading of from 1 34 to 1 36. Experiments show that soaking lowers the percentage of proteins and solids The normal figures are from 19 to 24 per cent. for solids and from 14 to 16 per cent. for proteins Soaking lowers these figures to from 10 to 16 per cent. for solids and 9 to 11 per cent. for proteins Scallops collected in the markets in Boston showed that about half of them had been soaked—Pub Health Bull Massachusetts

THE OUTLOOK FOR BLOOD TRANSFUSION

Blood transfusion is likely to be a far more efficacious therapeutic procedure in the near future than it has been during the few years that have witnessed the introduction of a successful technic for the operation This statement is not intended to imply that successful transfusions have heretofore been rare or that the coming period is necessarily likely to witness an increasing number of applications of the method in practice But the technic has been rendered more satisfactory, easier of general application under difficult circumstances, and safer in its employment This aspect of the matter is exemplified in the introduction of syringe transfusion, a process easily repeated and involving little pain or trauma as compared with the original surgical method The necessary precautions have been studied and explained so that the dangers and complications of transfusion — such as those due to incompatible blood, dilatation of the heart and introduction of air — are readily preventable The fundamental importance of ascertaining the possibility of hemolysis or agglutination of the red blood cells of either donor or patient by the serum of the other is almost universally recognized and taken into account Further than all this is the fact that the indications for transfusion are being better understood so that, to quote recent writers, there is a tendency more and more to use it not as a means of last resort but as an ordinary therapeutic measure

In the case of any novel method of treatment, applicable to clinical medicine, the value of which depends in good part on statistical results and careful observation, a retrospect and a critical review are always of practical interest From a general summary of this sort prepared by Ottenberg and Libman[1] of the Mount Sinai Hospital, New York, we gain a decidedly helpful impression of the status of blood transfusion Their statistics cover nearly 200 cases, and thus derive considerable authority from the force of numbers The cases in which transfusion was apparently life-saving fall under the headings of acute anemia from hemorrhage, hemorrhagic diathesis, whether hereditary or acquired, grave chronic anemias, and poisoning In a goodly number of other cases, transfusion was not an emergency measure, but was performed on patients whose general condition had been seriously impaired by chronic disease In more than forty of these, great improvement followed the transfusion, even when the recovery from the disease itself was not complete Expressed in a statistical way, 45 per cent of the transfusion cases were successful in that the condition of the patient was greatly improved This includes 22 per cent in which the procedure was life-saving In about half of the attempted transfusions, no good was accomplished

These are the bare figures Some details deserve to be quoted for the light which they throw on the value of the method In almost all of the cases of gastric or duodenal ulcer, the hemorrhages stopped after transfusion The danger of increasing the bleeding by raising the blood pressure through transfusion during active hemorrhage must not be overlooked The cases in which it appears actually to be checked are those of repeated or prolonged hemorrhage Blood which can form normal thrombi is supplied Transfusion is also worth trying as a temporizing measure in other forms of prolonged hemorrhage in which there is nutritional disturbance, as in severe dysentery Ottenberg and Libman insist that transfusion should be tried more often than it has been in the emergencies of severe typhoid Here, too, it not only replaces lost blood but also may help to check hemorrhage With the first appearance of blood in the stools of this disease, preparation should be made so that a transfusion can be done, if needed, at very short notice, for in the typhoid state and in very protracted cases, it may be life-saving Transfusion seems well indicated in the conditions arising from ectopic gestation

The occasional usefulness of transfusion in connection with surgical operations, particularly for postoperative hemorrhage, was early considered and is quite generally understood In surgical shock the results are frankly disappointing, so that, despite the hopes once awakened, transfusion cannot be relied on as a remedy In hemorrhagic disease, and particularly hemophilia, the results have been noteworthy Here transfusion may actually be termed a specific therapy for the control of hemorrhage Where serum treatment — subcutaneous, intravenous or local use of human, horse or rabbit serum — has been without remedial effect, transfusion has repeatedly supplied a lacking element and stopped hemorrhage Ottenberg and Libman are so impressed with its value in hemophilia, in which the majority of the sufferers never reach adult life, that they look on transfusion as offering a new hope to those afflicted with this disease of high mortality They suggest that every individual known to have hemophilia ought to have at his com-mind several persons whose blood by previous tests is known to be compatible with that of the patient and who are willing, when called on, to act as donors. The syringe method does not injure the veins, and allows for any number of prompt transfusions. In consideration of this, the New York investigators believe that the majority of hemophiliacs might be enabled to lead a life of normal duration.

---

[1] Ottenberg, R, and Libman, E Blood Transfusion Indications, Results, General Management, Am Jour Med Sc., 1915, cl, 36

With regard to pernicious anemia, no one can be expected in the present state of knowledge to speak with emphatic certainty of any satisfactory management of this insidious disease. Ottenberg and Libman believe that transfusions should be resorted to early, and persistently repeated, to prevent the development of a marked grade of anemia. They regard transfusion as the best remedy; it never cures, but it leads to remissions in about half of the cases. When these fail, splenectomy can still be resorted to in accord with the dictates of increasing experiences. In the infectious diseases there are numerous possible fields of application for transfusion which deserve very careful study and are likely to reward it. Even in such a serious condition as endocardial infection, transfusion offers some promise. It puts the organs into better condition to respond to other methods of therapy, and inasmuch as there is a tendency in endocarditis for the patients to become spontaneously bacteria-free, the procedure may be worth trying repeatedly.

RESPONSES OF THE RESPIRATORY CENTER

It has long been known that carbon dioxid "stimulates" the respiratory center, that is, causes an increase in the rate or depth, or both, of the respiratory movements. The result is an increase in the amount of air breathed in a given time. Researches of recent years have shown that this action of carbon dioxid is in reality due to the hydrogen ions of the carbonic acid (H_2CO_3) formed when carbon dioxid is dissolved in water or in a fluid like the blood. Other acids reaching the blood have the same effect.

Loewy showed, twenty-five years ago, that within certain limits there is a parallelism between the percentage of carbon dioxid in the inspired air and the volume of air breathed. Thus the total amount of air breathed doubled when the subject inhaled air containing sufficient carbon dioxid to raise the concentration of carbon dioxid in the expired air to between 5 and 6 per cent. Loewy and others have taken advantage of this reaction to test the effects of drugs on the excitability of the respiratory center. As an illustration of the results obtained, the effect of morphin may be cited. After a small dose of morphin, a much greater concentration of carbon dioxid in the inspired air is required to cause a given increase in the amount of air breathed; in other words, the excitability of the respiratory center has been lowered by the drug. Since the excitability of the respiratory center to other stimuli (through sensory nerves, for example) is similarly lowered by morphin, the mode of action of opiates as respiratory sedatives is obvious.

Means, Newburgh and Porter[1] have recently applied the same method to a study of the condition of the respiratory center in experimental pneumonia. They compared the effects of different concentrations of carbon dioxid on the volume of air breathed by normal cats and by cats in which pneumonia had been experimentally produced. In all cases the breathing of carbon dioxid had a much greater stimulating action on the respiratory center of the normal cats than on that of the cats with pneumonia; there was a marked depression of the excitability of the respiratory center in pneumonia, especially marked in those animals which were near death, but also very pronounced in those which were only moderately ill. Aside from their great scientific interest, these results would seem to have important practical bearings. Thus, as was stated above, morphin has the same effect on the respiratory center as does pneumonia; this suggests that great caution should be used in the administration of opiates to patients ill with pneumonia.

Peabody[2] has recently applied this principle (the effect of carbon dioxid on the respiratory center) in an effort to obtain further light on the mechanism of the production of dyspnea in certain cases of cardiac and of cardiorenal disease. He found that, whereas in normal individuals the total ventilation was doubled only when the concentration of the carbon dioxid had risen to between 4.2 and 5.4 per cent., in certain of the pathologic cases the ventilation was doubled when the inspired air contained only 2 or 3 per cent. of carbon dioxid. This result does not, however, show that the excitability of the respiratory center has been directly affected in these pathologic conditions, for these results were obtained only in those cases in which a condition of acidosis was present; cases without acidosis or cases in which the acidosis had been combated by the administration of alkali reacted to an increase in the carbon dioxid content of the inspired air in a normal manner. This is another illustration of the fact that in certain cases of cardiac, and especially of cardiorenal disease, the dyspnea is due in part to an accompanying condition of acidosis.

Observations of this character are of great importance in explaining the condition and responses, under normal and pathologic conditions, of one of the most vital but in many respects least understood of the functions of the body, that of respiration.

THE ABSORPTION OF CHOLESTEROL

The peculiar lipoidal compound cholesterol, or cholesterin, as it is still sometimes called, has long been known to physiologic chemists, yet, aside from those features of its chemical structure which mark it as an alcohol, and certain other incidental characteristics, the real make-up of this complex substance is almost as much of a puzzle as it was two or three decades ago Cholesterol has not been synthetized by the chemist, but its widespread occurrence in nature among animals and, in closely related form at least, among plants certainly foretells the biologic importance of the substance

In the animal organism, cholesterol occurs not only free, but also combined with fatty acids in the form of esters Cholesteryl oleate and palmitate are known as constituents of the blood along with the alcohol itself In the nervous system a large content of free cholesterol is always present Pathologic structures may also contain it Until quite recently it has been debated whether cholesterol can be formed anew in the adult organism or whether the latter is dependent on exogenous sources for its supply Today there is, we believe, a fair agreement that the cholesterol of the body has its origin in the food and not in actual synthesis within the tissues English investigators, in particular, have shown definitely that feeding cholesterol either as such or in the form of its esters results in an increase in the blood content of both forms

The extension of the physiology of cholesterol has long demanded a better elucidation of the mode and path of absorption of the substance, and some indication of the formation of its esters Dr J H Mueller,[1] of the Department of Pathology at Columbia University, College of Physicians and Surgeons, has followed the actual absorption of cholesterol and its derivatives from the alimentary tract into the lymph stream of the thoracic duct Reasoning that, since fatty material enters the blood stream by way of the lymphatics, one might expect to find cholesterol also absorbed in this way, because of its solubility in fats and its insolubility in aqueous mediums, Mueller analyzed the lymph of experimental animals before and after feeding the lipoidal product The figures show that cholesterol is readily absorbed from the intestinal tract through the chyle, and may be recognized in the contents of the thoracic duct When cholesterol is fed entirely in the free condition, a portion is esterified during the absorption, and appears so in the chyle Cholesterol esters, in turn, may be split into their component groups Hence, either in the intestinal contents or in the wall of the intestine, processes of esterification or hydrolytic cleavage may take place As a result, the absorbed product shows approximately the same proportion of free cholesterol to ester as is found normally in the chyle Evidently this ratio tends to be preserved The findings of Mueller do not prove directly that no cholesterol is absorbed immediately into the blood, but the quantitative data make such a process appear as a more unlikely probability

THEORIES OF DELIRIUM TREMENS

Since the Harrison Narcotic Law went into effect, many drug habitues, having exhausted their supply and failing to obtain more, have turned to alcohol as a substitute In some who had been drinking for years, the sudden and marked increase in the amount of liquor consumed has led to the frequent occurrence of delirium tremens This brings up anew the question as to what is the final factor in the production of delirium tremens

Chronic alcoholic poisoning produces well-known changes in the central and peripheral nervous system Among these are vacuolization and high grade degeneration of the nerve cells with atrophy and shriveling, fatty infiltration of the medullary substance, dissolution of the chromatin structure, inflammatory infiltration of the pia, internal hydrocephalus, and degeneration of the peripheral nerves Cases of delirium tremens may present the same changes, or the chronic changes may be of higher grade Even instances of Korsakoff's psychosis may differ from chronic alcoholism only in a more severe change in the ganglion cells As yet, however, no changes have been found in the brain which explain why a man who has been drinking for years suddenly develops a delirium which runs a definite course of from three to five days or even longer

It has been thought that delirium tremens is an acute infection occurring in chronic alcoholics Nevertheless, many cases run their entire course without fever, and Nonne[1] found blood cultures negative in fifteen consecutive cases examined by him Dollken[2] believes that continued drinking of alcohol results in the production of a poisonous substance in the brain itself, and that an accumulation or concentration of this substance produces delirium tremens Jacobson[3] explains the delirium as an autointoxication, the toxin arising from the pneumococcus gaining entrance through the liver, the kidney or the intestinal tract, and acting on a brain which has been poisoned over a long period of time by alcohol The view of Hertz[4] differs from this in that the supposed poison which precipitates the delirium comes from an insufficiency on the part of the kidney, this in turn being due to the acute nephritis which usually accompanies delirium

tremens That albuminuria is present and seemingly dependent on this delirium was long ago maintained by Fürstner,[5] and has been noted repeatedly since According to Bonhoefter,[6] chronic alteration in the intestinal tract is responsible for the elaboration of poison which is normally excreted through the lungs In diseases of the lungs, and especially in pneumonia, an altered gas exchange occurs, the excretion of this poison is hindered and delirium tremens is the result Wagner von Jauregg[7] believes that the liver rather than the lungs is the organ which fails to eliminate the poison elaborated in the gastro-intestinal tract, and he thinks that this failure is due to the changes occurring in the liver in chronic alcoholism Kauffmann[8] has asserted that this poison is a carbon derivative acting on a medulla altered as a result of chronic alcoholism He believes that the delirium will persist until the production of this carbon derivative stops

All of these theories demand as a preliminary condition a poisoned and permanently altered central nervous system on which a poison acts The objection is raised that many chronic drinkers develop marked brain and visceral changes and yet never suffer a delirium In answer it has been suggested that, in patients who acquire delirium tremens, the brain has undergone some special change As a result of this change, an autointoxication produces a delirium, or one may assume the view of Raimann,[9] that for each poison elaborated in chronic drinkers, a special psychosis results Thus one poison causes delirium tremens, a second Korsakoff's psychosis, and a third the poliomyelitis superior acuta of Wernicke

The possibility that delirium is due to an increase in the pressure and amount of the spinal fluid has recently been considered[10] There are two other theories of special interest, the first on account of its ingenuity, the second on account of its bearing on statistical evidence Jauregg[11] of Vienna assumes that the body of chronic alcoholics protects itself by the production of an antialcohol which is of the nature of an antitoxin When a hard drinker suddenly stops taking alcohol, this antialcoholic substance, having no alcohol to which to affix itself, acts on the body in such a manner as to produce delirium tremens Hare[12] maintains that the development of delirium is due to a sudden fall in the amount of alcohol circulating in the blood of alcoholics His evidence is drawn from a study of seventy-five cases of delirium tremens, in nearly all of which there was a great reduction in the amount of alcohol absorbed prior to the onset of delirium In many of these instances the alcohol was withheld, in others vomiting prevented its absorption

Numerous objections have been raised to each of these theories The views concerning poisons and autointoxications have been vigorously attacked because there is as yet no definite proof that a poison is elaborated There are already adversaries to the recent notions concerning an increased pressure of the spinal fluid and the fall of alcohol in the circulating blood, all of which indicates that much work remains to be done before the final answer to the problem is reached

A NATIONAL BOARD OF MEDICAL EXAMINERS

Preliminary steps have been taken for the organization of a national board of medical examiners, to be established with the government medical services as a nucleus A body composed of fifteen physicians,[1] including representatives of the government services, is now at work on the details by which a working organization can be established The original intention was to have representatives on the board from a number of prominent medical organizations, including the American Medical Association, but at a meeting held recently in Washington it was decided that no organizations of physicians as such should be directly represented on the board We believe that this decision is a wise one, even though it eliminates the American Medical Association from direct representation on the board The matter came before the House of Delegates of the American Medical Association last June, as it was a part of the president's address, the only action taken was to refer the matter to the Council on Medical Education for further consideration It is proposed to make this matter a subject of general discussion at the conference of the Council to be held in Chicago, February 7, next A symposium on the subject is being arranged, and several prominent speakers, including representatives of the government services and state licensing boards, will participate

That there is need of a national board of medical examiners practically all are agreed Such a board must be essentially a voluntary organization — unless created in some way by the national government — the purpose of which must be not to displace but to cooperate with the various state medical licensing boards It is essential that the educational qualifications required of those who are to take the examination should be as high as the highest required by any state board The methods of verifying and evaluating credentials of educational qualifications must be so thorough as to make it impossible for any poorly qualified individual to slip through Its examination must be of such unquestioned thoroughness as to make it worthy of recognition by all state licensing boards If these conditions obtain, and especially if the certificate of this board is accepted for admission to the three government services in lieu of the examinations at present required, all state licensing boards would undoubtedly in time recognize it as an acceptable qualification for the license in their various commonwealths Progress in this respect would be a parallel to what has taken place in Canada, where, following the organization of the Medical Council of Canada, it was necessary to secure recognition of it in each province of the Dominion

Current Comment

A THEORY OF THE PRODUCTION OF DIURESIS

Some time ago Cow, of the pharmacological laboratory at Cambridge, England, made the interesting and unexpected observation that a strictly physiologic quantity of saline solution or of water, which may fail to produce any increase in diuresis when it is injected directly into the circulation, may nevertheless give rise to a distinct increase when administered by the mouth Usually, intravenous injections of active products are more potent than oral administration Hence the suggestion that there exists in the gastro-intestinal mucous membrane a substance which presumably is taken up by water during absorption from the alimentary tract, and that this substance, either directly or indirectly, is largely concerned in the production of diuresis[1] More recent investigations by the same author[2] have elucidated the probable sequence of events concerned in this phenomenon They show that perfusion of the kidney with extracts of the duodenal mucous membrane gives rise to diuresis provided the fluid has previously been passed through the general circulation or through the circulation of the head and neck Circulation through a headless subject is ineffective We need not here detail the evidence which furnished the explanation It points to the pituitary body, an organ which gives an extract of known diuretic action, as the connecting link between the introduction of the duodenal mucous membrane extract and the subsequent diuresis Ingestion of water or saline solution may thus be assumed to lead to an absorption of some substance contained in the gastro-intestinal mucous membrane which in turn stimulates the pituitary to discharge the product that induces diuresis The suggested succession of events reminds one of the sequence by which gastric chyme is believed to liberate in the intestinal wall the secretin which thereupon provokes the flow of pancreatic juice In the case of diuresis cited there is a duplication of hormone effects Several phenomena are in accord with the hypothesis of Cow The long latent period which occurs between an intravenous injection of duodenal membrane extracts and the onset of increased diuresis is explicable on the basis of the time required for the succession of indirect events including the pituitary functioning It also indicates why in otherwise intact experimental animals whose pituitary bodies have been destroyed, intravenous injections of duodenal mucous membrane extracts produce no characteristic diuretic effects such as follow when the pituitary is intact The suggested interrelation between the mucosa of the intestine and the pituitary is an unexpected discovery which, if it shall be confirmed, adds another to the instances of remarkable "long-distance" chemical regulative mechanisms in the organism

THE SOCIAL TREATMENT OF TUBERCULOSIS

The significant feature of the Home Hospital experiment of the New York Association for Improving the Condition of the Poor[1] is its recognition of the fact that tuberculosis is a social as well as an individual disorder, affecting people's lives at many points, and therefore to be attacked coincidently from several sides The New York City Department of Health, among others, is doing work based on a recognition of this fact Mrs Herman M Biggs, wife of the commissioner of health of New York State, in an address delivered before the New York Association of Tuberculosis Clinics,[2] describes the social activities of the Chelsea Clinic, located in the west side tenement district of New York A class in dietetics gives instructions to mothers and other homemakers on the values of foodstuffs and the preparation of simple, nourishing, inexpensive foods Trained dietitians are sent into the homes of tuberculous families under observation, to teach the members of the family how to market and cook Families are encouraged and, so far as possible, assisted to improve their housing conditions, but this, though most important, is expensive and difficult Physical training classes for the children have been in operation for about two years, and the results of corrective and developmental exercises have been most encouraging A nursery, a kindergarten and a roofgarden, where the children spend most of their time, furnish means of removing them from tuberculous homes during the day The children take

[2] Reported in the Modern Hospital, September, 1915, p 203

long naps, and are given a nourishing supper before their return home Mrs Biggs does not give figures on comparative cost and efficiency, such as were furnished by the Association for Improving the Condition of the Poor with regard to the Home Hospital A comparison would doubtless be difficult to make, but it would be instructive to have some of the concrete results of this interesting work presented for the guidance of tuberculosis workers elsewhere

ANOTHER TRAGEDY OF UNPREPAREDNESS

In a football game at St Louis several weeks ago, one of the players received an injury to the cervical spine and was taken to the City Hospital After careful examination it was determined that surgical interference was not indicated, in that fragments of the vertebra were not then pressing on the cord, that the character of the injury made the patient's condition practically hopeless, and that the treatment indicated was absolute quiet and immobilization The parents of the boy were frankly told the seriousness of the injury In the face of these conditions, according to the *Journal of the Missouri State Medical Association*,[1] an osteopath, who had been engaged by the father, wanted to treat the patient immediately The surgeon in charge, fearing injudicious handling which would deprive the patient of any existing chance for recovery, refused to permit the osteopath's treatment The osteopath, accompanied by the boy's father, then obtained an order from the mayor to the hospital commissioner, relieving the hospital physicians from further responsibility and permitting the osteopath to "try to save the patient as the doctors had 'given him up'" Says the Missouri journal

> For five days the patient had been resting quietly with a gradual lessening of the effects of the frightful shock from the hemorrhage into the cord Then the osteopath applied a jury-mast to the victim's head which resulted in renewed shock, a scream and a plea from the patient to remove the apparatus The patient became cyanotic. The extension was removed on account of the patient's bad condition Death followed about two hours later

The necropsy report showed that death was due to "hemorrhage into the cord and fracture of the cervical vertebrae," thus supporting the diagnosis of the physicians and proving that their treatment had been correct The *Journal* continues

> Now it seems clear that the major and the director of public welfare actually took charge of a poor unfortunate who was receiving the best possible care which could be provided in a metropolis and noted medical center They dismissed the skilled attendants who were honest and had informed the relatives of the actual state of affairs and turned the patient over to the distracted and deluded father and mother and an arrogant, boastful osteopath

Here, it seems, is another instance in which the delicate watch was given over for repairs, not to a skilled watchmaker, but to a blacksmith The change of the patient from a condition of quiet restfulness, with its possible chance for recovery, to one of sudden pain, shock and speedy death was too prompt to be interpreted otherwise than as due to the use of methods entirely unwarranted by the conditions The safety of the patient demands that whoever assumes the role of the physician must have had sufficient medical training to know when such treatment is best and when it is bound to do more harm than good

SECRETORY NERVES FOR THE KIDNEY

The anatomic features of the innervation of the kidney are well understood, and the relation of the nervous system to its blood supply has been fairly well elucidated in recent years Vasomotor impulses which change the circulation in the renal organs promptly affect the condition of diuresis in them From the richness of their nerve supply as well as by analogy with other active glands, one might expect the kidneys to contain true secretory nerves The answer to this question has been difficult to secure, particularly because of the sensitiveness of the kidney structures to even minor variations in the blood supply and arterial pressure, as well as to the presence of small quantities of chemical substances in the blood stream Only when these variables are controlled and accounted for can alterations in urine production be charged to nervous stimulation The remarkable adaptability of the kidney function to changes in the composition of the fluid perfusing it is undoubtedly in large measure a response to chemical factors Nevertheless there have been occasional suggestions of an influence exerted by the nervous system directly on the active cells Some time ago, experiments by Asher and Pearce[1] were cited which these investigators interpreted as demonstrating the presence of renal secretory fibers in the vagus nerve The technical difficulties of the investigation were very great, and the conclusions have not remained unchallenged Asher and Pearce depended on the rate of urine formation for evidence of the changes in the functional activities of the renal cells under vagus stimulation Pearce and Carter,[2] of the physiologic laboratory at the Western Reserve University in Cleveland, have sought for corroboratory evidence of renal activity under vagus stimulation in another manner Cellular metabolism is well known to be attended with increased consumption of oxygen The action of some diuretics, for example, is accompanied by increased gaseous metabolism of the kidney This factor was investigated, therefore, in relation to vagus stimulation Pearce and Carter failed to obtain evidence of any increased gaseous exchange, and their newest evidence accordingly speaks against the supposed existence of renal secretory fibers in the vagus nerve

Safe Schools—Public schools are a public trust When the parent delivers his child to their care he has a right to insist that the child under the supervision of the school authorities shall be safe from harm and will at least be handed back to him in as good condition as he was at first—*Wisconsin State Board of Health Bulletin*

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest, such as relate to society activities new hospitals, education, public health, etc)

ALABAMA

Personal.—Dr John Little, Tuscaloosa, has been reelected treasurer, and Dr William M Faulk, Tuscaloosa, secretary of the board of trustees of the Alabama Insane Hospital

State Tuberculosis Commission Appointed—The governor has appointed the following as the Alabama Tuberculosis Commission created by the last session of the legislature Dr William H Sanders, Montgomery, ex-officio, and Drs Cabot Lull, Andrew L Stabler and Benjamin L Wyman, Birmingham, R C Long, Carbon Hill, Rev George E Birmingham and Messrs J T Ashcraft, Florence, A R Brindley, Gadsden, and E R Brown, Birmingham

Health Campaign in Etowah County—State Health Officer Sanders has notified Dr Claude L Murphree, Gadsden, health officer of Etowah County, that he intends shortly to inaugurate a campaign for better sanitation and health in the county, and has asked for the names of ten places that will be likely to give audience to such a campaign The county will be properly circularized and experts will urge the adoption of methods of sanitation which will bring about a revolution in health conditions

Hospital Notes—Work will shortly be started on the addition to the Birmingham Infirmary, West End The addition will be in two units, 50 by 100 feet and three stories in height and in them will be housed a maternity ward and a ward for medical treatment——A meeting was held in the court house at Clanton, November 20, to make arrangements for the erection of a hospital building at Clanton, for Chilton County——A mass meeting of citizens of Dothan and Houston counties was held November 8, at the State Hospital at Dothan to raise $40,000 for building and equipping a modern general hospital for the city——The southside jail, Birmingham, has been transformed into a charity hospital under the care of the city physician

ARKANSAS

State Society to Meet in Texarkana—The annual meeting of the Arkansas Medical Society will be held in Texarkana early in May next

Smallpox—An epidemic of smallpox exists at Heber Springs According to Dr Charles W Garrison, state health officer, more than fifty cases have developed in the town

State Antituberculosis Society—At a meeting of the State Society for the Study and Prevention of Tuberculosis in Little Rock, November 24, the local society was absorbed and new officers were elected On the new board of directors appear the names of the following physicians Drs St Cloud Cooper, Fort Smith, and Clinton P Meriwether, Charles R Chestnut, and Charles W Garrison, Little Rock

General Hospital Favored—The closing session of the third annual conference of health officers of Arkansas, November 23, was a joint meeting between the health officers and the faculty members and alumni of the University of Arkansas, at which a resolution favoring the establishment of a state general hospital was unanimously adopted A committee of five physicians was appointed to work out a plan for establishing a hospital and to form organizations in each county to work for the passage of a law making appropriations for its maintenance

Personal—Dr Frank B Young, superintendent of the State Hospital for Nervous Diseases, Little Rock, has resigned to take effect November 31 The board of control accepted his resignation and tendered the position to Dr James L Greene, Hot Springs, whom Dr Young succeeded——In honor of his seventieth birthday Dr M Donaldson, Rector, was given a banquet by local physicians and druggists, November 18——Dr Delparde W Roberts, senior physician of the State Hospital for Nervous Diseases, Little Rock, has resigned to accept a similar position at the Sacred Heart Hospital near Milwaukee

ILLINOIS

Water Survey Chemist Transferred—H P Corson, instructor in sanitary chemistry and bacteriology for the Illinois State Water Survey, has been appointed sanitary chemist in the United States Public Health Service at Grove City, Pa.

New Dispensary Opened—A free dispensary has been opened in connection with St John's House, Ridgely, Springfield The institution will be open on Saturdays from 10 to 12 o'clock, and a physician and nurse will be in regular attendance

Epidemic Diseases—The public schools of Sparland have been closed on account of the presence of smallpox——The schools in DuQuoin have been dismissed and the buildings fumigated on account of the presence of twenty-five cases of diphtheria in the city

Personal—Dr Warren R Rainey, Salem, a member of the Chicago unit, has returned from Flanders——Dr Henry S Metcalf, Mt Carroll, is reported to be seriously ill with septicemia in the Freeport General Hospital——Dr Wilfred H Gardner, Bloomington, who has been serving as surgeon in a British Hospital in London, for almost a year, sailed for the United States December 8——Dr Marion E Reed, East St Louis, has returned after eight years in the Samoan Islands——Dr Clarence M Cheadle, Ashton, is at Nish, Serbia, recovering from typhus fever——Dr Emil Lofgren, Rockford, has been elected president of the Winnebago County Antituberculosis Association——Dr John P Benson has been elected president and Dr Herbert S Worthley, secretary, of the medical staff of St Joseph's Hospital, Joliet——Dr William C Bridge, Elgin, fell on a slippery pavement, November 22, receiving a severe scalp wound

Chicago

Physicians' Club Meets—The Physicians' Club held its second dinner of the year, November 23, when the psychopathic situation was discussed Chief Justice Harry Olson of the municipal court presided

Hospital Addition Approved—Plans for a $1,000,000 addition to the Cook County Hospital which is to contain a model hospital kitchen, have been approved by members of the Board of County Commissioners

New Charities Building Dedicated—The building at Wood and Selden Streets, erected at a cost of $200,000 by Julius Rosenwald, housing the West Side Charities and to be used as a general administration building by the Associated Jewish Charities, was dedicated with formal ceremonies on November 28

Annual Address at Institute of Medicine—At the annual meeting of the Institute of Medicine of Chicago, December 7, Drs Thomas J Watkins, Robert B Preble and Frank Cary were elected members of the board of governors for a term of five years The annual address was delivered by the president, Dr William E Quine, on "Medical Teachers and Teaching," and Professor Stieglitz of the University of Chicago and Professor Kendall of Northwestern University spoke on the "Relation of the Institute to Medical Progress"

Children's Health Crusade—The December issue of the *Open Air Smile,* the organ of the Elizabeth McCormick Open Air School, is devoted to the Children's Health Crusade Day, December 10 The superintendent of schools has requested teachers in all schools to see that this journal is distributed to each child and that it be used at reading lessons and at convocation exercises and as a test for health talks on that day A similar use will be made of this issue of the periodical in the parochial schools of the city

Personal—Dr William A Clark sailed for Belgium, December 4, to be director of an American Red Cross unit at Hospital L'Ocean, La Panne, Belgium——Dr Maurice B Wallin, ambulance surgeon of the West Chicago Avenue Police Station, was injured in a collision between his automobile and a street car, November 30——Dr John Dill Robertson has been appointed chairman of the committee on sanitation of the Chicago Bundle Days Committee—Dr Irving F Stein has been appointed associate in obstetrics on the staff of the Michael Reese Hospital——Dr Otto T Freer delivered an address before the German Medical Society of New York on December 6 His subject was "Opening the Frontal Sinus Through the Nose"

IOWA

Hospital News—Dr George W Franklin has opened a hospital in Jefferson The institution has five rooms and accommodation for seven patients——Dr Joseph J Meehan has purchased the Young property at Denison and will remodel the house for a private hospital or sanatorium

New Antituberculosis Societies—The Sioux City and Woodbury County Society for the Prevention of Tuberculosis was organized November 12 to take over the work that has been performed by the Visiting Nurses' Association——A society for the prevention of tuberculosis was organized at Boone November 23, at which Dr Albert B Deering was elected president

Personal.—Dr W T Graham, superintendent of the Methodist Hospital, Des Moines, has been placed in charge of the hospital of the state university, Iowa City——Dr Guilford H Sumner, Des Moines, secretary of the State Board of Health is reported to be ill in a hospital in Ruthven——Dr J Robert Wright has been appointed assistant superintendent of the State Hospital for Inebriates Knoxville, succeeding Dr J Van Meter, who has accepted a position at the Clarinda State Hospital

Vital Statistics—Iowa, with a population of 2,225 000, in August had 1 534 deaths According to the report of the State Board of Health 184 of these deaths were in children under 1 year, 55 in children from 1 to 5 years, 33 from 5 to 10 years There were 23 deaths of persons 90 years of age or over The number of deaths in state institutions was 30 There were no deaths in the state during the month from malaria smallpox or rabies There were 21 deaths from typhoid fever, 7 from measles 8 from whooping cough, 2 from pellagra 5 from tetanus 169 from cancer and other malignant tumors, 167 from organic diseases of the heart, 106 from nephritis and other diseases of the kidneys, 17 from puerperal septicemia and other puerperal diseases There were twenty-three suicides

KENTUCKY

New Hospitals—The Citizens' National Hospital, a continuation of the hospital of the old Louisville National Medical College was reopened in new quarters at 1525 W Chestnut Street Louisville November 9——At a meeting of the Clark County Medical Society at Winchester November 5, it was announced that $17 500 was now available for the county hospital project The Fiscal Court has made a pledge of $5 000 as soon as $25 000 has been raised The society now asks that this amount be reduced so that the court's donation may become available when $20 000 has been raised——A meeting was held in Mt Sterling November 6, in the interest of a hospital for Montgomery County for which $25 000 is required A committee was appointed to visit Harrodsburg and inspect the new hospital there——The new Harrodsburg Hospital erected at a cost of $13 000 was formally dedicated October 22 Dr Lewis S McMurtry, Louisville, delivered the principal address

LOUISIANA

Health Exhibit Car in Texas—The educational hygiene exhibit car of the Louisiana State Board of Health was on exhibit in Dallas during the meeting of the Southern Medical Association

Quarantine Not to be Moved—Surgeon-General Rupert Blue U S P H S after an investigation of the quarantine station, has decided that it is unnecessary to remove the station closer to New Orleans

Personal.—Dr Joseph D Tuten has succeeded Dr S George Kreeger resigned, as president of the Board of Health of Lake Charles——At a meeting of the Fifth District Medical Society at Tallulah a medal was presented to Dr Thomas E Wright Monroe for original research in the treatment of malaria by the intravenous injection of quinin The medal was presented by Dr Oswald W Cosby on behalf of the society——Dr Clarence Pierson superintendent of the East Louisiana Hospital for the Insane, Jackson, has resigned——Dr E M Ellis Crowley has been appointed a member of the State Board of Health succeeding Dr Henry B White, Gueydan, who has been made state medical inspector

MARYLAND

Hospital Dedicated—The new Emergency Hospital Easton, was formally dedicated November 23

Personal.—Dr Nathan G Keirle has been reappointed chief medical examiner of Baltimore city by Health Commissioner John D Blake Dr Keirle has held this position for many years——Dr Henry G Branham was also reappointed assistant chief medical examiner——Dr Henry O Reik gave the third of a series of lectures during the past week the subject being 'Our National Parks —Dr T C Janeway has been elected president of the Baltimore community workshop

Health Department Gets Additional Appropriation—Health Commissioner Blake has been allowed practically all he asked for in the way of appropriation, except that required for a new hospital building at Quarantine and an additional ward building and a home for nurses at Sydnum He was, however, given an appropriation for an additional tuberculosis dispensary in North Baltimore The total increase will aggregate about $40,000

Society Meets at Training School—The Baltimore County Medical Society held a meeting November 17 at the Rosewood Training School, Owings Mills The Society was entertained at luncheon by Dr Frank W Keating, superintendent of the school, and later made an inspection of the building under the guidance of Dr Keating and his assistant Clinics were afterward held by Drs Keating and Kenneth B Jones, Baltimore

Charity Campaign Opened—A campaign to raise $225,000 for the support of the organizations composing the Alliance of Charitable and Social Agencies of Baltimore was begun during the past week The campaign was organized at a dinner held at the Emerson Hotel when various teams were appointed to secure the money in the time limit, two weeks A luncheon is held every day at the City Club, at which time each team reports the results of its day's work. Thus far over $77 000 has been raised

University to Ask State Funds—The University of Maryland will ask the legislature at its next session to grant a substantial annual appropriation Of recent years the institution has received no money from the state except the grants to the hospital and St John's College which is an integral part of the university Since the recent consolidation of the university with the College of Physicians and Surgeons, there has been greater need for funds and although the legislature appropriated $15 000 for the school in 1915 and a like sum in 1916 the money is said not to have been paid to the institution

MASSACHUSETTS

Cancer Clinic to be Established—Carney Hospital, Boston announces the establishment of a clinic for the treatment of cancer and other malignant diseases by the use of radium The clinic will be opened late this month or early in January It will be under the supervision of Dr John T Bottomley and the radium for use has been donated by M Douglass Flattery of Boston

School Physicians Named—The school committee of Boston has appointed forty physicians as inspectors of schoolchildren Each physician will receive a salary of $504, excepting one later to be selected who will act in the employment certificate office and will receive $900 a year These appointees will take the place of the health board physicians who formerly were assigned to duty in public schools

Honor Old Members—Drs Edward Cowles, Plymouth, Samuel H Durgin Duxbury, A Elliott Payne, Brockton, Horatio F Copeland Whitman, and Calvin Pratt Bridgewater, all of whom have been in practice more than fifty years and all of whom in addition, were veterans of the Civil War and are still engaged in active practice were guests of honor at a banquet given by the Plymouth Medical Society at Brockton November 23 Dr Gilman Osgood, Rockland, officiated as toastmaster

Decennial of Social Service Department.—The tenth anniversary meeting of the social service department of the Massachusetts General Hospital was held in the institution November 30 Dr Richard C Cabot presiding The program includes papers by Mr Homer Folks on "Humanizing the Institution , by Mrs William H Lathrop on 'The Responsibilities of Popularity" and a discussion by Dr Richards Eustis, Cambridge Miss Clara M Welsh and Thekla Andren on 'What Was Done for Rebecca Aronobsky by Those Who Did It," an illustration of the care of heart disease in children

Personal—Dr Hugh Cabot Boston, read a paper at the monthly meeting of the surgical section of the Hartford (Conn) Medical Society November 22——Dr Stanley S Osburn Peabody who has been on duty at Uskub Serbia is believed to have been taken prisoner by the Bulgarians——Dr George A Powers, Worcester, has been appointed associate medical examiner in Worcester County and Dr William O Faxon, Stoughton, has been reappointed medical examiner for Norfolk County——Dr Robert Williamson Lovett, Boston, has been elected John B and Buckminster Brown professor of orthopedic surgery in Harvard Medical School

MINNESOTA

Anthrax—A death from anthrax was reported in the returns to the State Board of Health for October, in the person of a farmer's wife at Rapidan, Blue Earth County, who was said to have been stung on the cheek by a bee or wasp The diagnosis was made by two physicians of Winona The State Board was not notified of the case until the woman's death

Territory Served by Mankato Laboratory—The State Board of Health has authorized the extension of the territory served by the Mankato Branch Laboratory This will include all the counties of Lincoln, Lyon, Redwood, Blue Earth, Brown, Nicollet, Rock, Nobles, Jackson, Martin and Faribault and portions of Yellow Medicine, LeSueur and Waseca counties The examinations made by the laboratory include sputum examinations, the Widal test and cultures for diagnosis and release from quarantine for diphtheria

Sanatorium Opened—The new tuberculosis sanatorium for Goodhue County, erected at a cost of $36,000 at Mineral Springs, near Cannon Falls, which will accommodate from thirty-five to forty patients, has been officially dedicated and is open to receive patients With the opening of this institution, four similar sanatoriums are now in operation, and ten others under construction——At the state sale of lands held at Brainerd, November 20, the State Fish Hatchery, Deerwood, was sold at its appraised valuation to the Crow Wing-Aitkin County Tuberculosis Sanatorium Commission The tract of land purchased includes 44¼ acres, with an eight-room two-story modern house The site is about 2 miles from Deerwood, near the Northern Pacific and Soo railways

Personal—Dr William R Bagley has resumed the practice of medicine in Duluth, after ranching in Oregon for five years——Dr James S Gilfillan, St Paul, was operated on for appendicitis in St Luke's Hospital in that city, December 1——Dr Carl A Scherer, Minneapolis, has moved to Fargo N D——Dr Ernest E Wells, Stillwater, coroner of Washington County, has assumed duties as sheriff on the death of that officer——Dr Gerald R Maloney, Belle Plaine, who has been ill, has recovered and resumed practice——Dr Frederick U Davis, Faribault, fractured his arm while cranking his automobile, November 14——Dr Edwin S Muir, Winona, who was operated on recently for appendicitis at the Winona General Hospital, is convalescent——Dr Honore D Valin, pathologist to the St Peter State Hospital, has resigned to accept a similar position at Fort Wayne, Ind——Drs Alexander H Brown and Thomas Lowe have associated themselves together to conduct a hospital to be known as the Pipestone Hospital——Dr Francis H Gambell was elected mayor of Thief River Falls at the recent election——Dr Holland T Ground of the staff of St Peter's State Hospital, who was operated on for appendicitis recently, is convalescent

NEW JERSEY

Water Company Held for Typhoid—The Mt Holly Water Company has been held responsible for causing typhoid fever during the outbreak in 1912, by a jury in the Burlington County Court which awarded $500 to William S Fryer in his suit to recover on account of the illness of his daughter This is the second successful suit against the water company

To Enlarge Tuberculosis Pavilion—Release from the crowded conditions of the Tuberculosis pavilion of the Soho Isolation Hospital, Newark, was promised, November 17, when the building committee of the board of freeholders eliminated the proposed new laboratory and substituted an additional ward for tuberculosis patients A bond issue of $60,000 has been asked for this purpose

Personal—Dr Joseph W Williams has been appointed city physician of Paterson to succeed Dr Paul E Rauschenbach, resigned——Dr James J McGuire, Trenton, has been appointed a member of the State Board of Medical Examiners, succeeding the late Dr Horace G Norton——Dr Jacob C Price, Branchville, has been appointed chief of the division of bureau administration, R B FitzRandolph, chief of the laboratory of hygiene, Dr A Clark Hunt, Metuchen, chief of the bureau of medical supervision, and Dr Millard Knowlton, Trenton, chief of the bureau of education and publicity of the State Department of Health——Dr Britton D Evans, Greystone Park, has been appointed chairman of the committee to prepare legislation for better care of the insane

NEW YORK

Personal—Dr C M Louis Hacker, Albany, has resigned as instructor in surgical pathology in the medical department of Union University, Albany

New York City

Home from Serbia—Dr George F Adair, Lynbrook, L I, has returned from Serbia, where he was in the service of the Serbian Red Cross

New Convalescent Home—The New York Association for Improving the Condition of the Poor has opened a convalescent home for wage-earners at Sea Breeze, Coney Island

Food Inspector Dies—Bayard Clarke Fuller, supervising inspector of food in the New York Department of Health from 1890 to 1911, died in the Post-Graduate Hospital, New York City, November 11, aged 52

Memorial to Dr Blackwell—A tablet in memory of Dr Emily Blackwell and her sister, Dr Elizabeth Blackwell, has been placed in the New York Infirmary for Women and Children, which was founded by them The bronze medallion on the tablet is the work of Victor D Brenner of New York

Leprosy—Two patients with leprosy have recently been the subject of investigation by physicians of the New York City Health Department It is said there are only ten known lepers in the city, all but three of whom are confined in institutions These three are under surveillance by the health board

Hospital for Wall Street Assured—The proposed Broad Street Hospital now seems assured, as it is announced that $50,000 has been raised This sum was fixed by other wealthy men in the Wall Street district as the necessary requirement before they would contribute, and makes the prospect of increased funds assuring

Academy of Medicine Elects Officers—At the stated meeting of the New York Academy of Medicine held December 2, officers were elected to fill expired vacancies The term of the president Dr Walter B James, does not expire until 1916 Dr George David Stewart was elected vice president and Dr Frederick T Van Beuren, Jr, recording secretary

Personal—Dr Mary M Crawford has returned from work with the American Ambulance, Paris——Dr Andrew J Gilmour lectured before the Vassar Institute, Poughkeepsie, November 30, on "Climbing the Canadian Alps"——Dr Robert C James has retired from active practice and will make his home near Lexington, Ky——Dr Sumner Everingham has returned from eight months' service in Serbia

Medical Relief Expedition for Germany—*The second medical relief expedition for Germany and Austria-Hungary, dispatched by the American Physicians Expeditions Committee, sailed for Copenhagen on the* *Hellig Olav,* November 25 The expedition is headed by Dr Fred Kammerer, who takes with him three other surgeons and six nurses and a complete outfit for the equipment of a hospital with 300 to 400 beds

Demand for Women Doctors Starts Campaign—The board of trustees of the New York Medical College and Hospital for Women has set out to raise $200,000 by Sept 1, 1916 The money will be used to erect what has been called "an emergency plant" This step is being taken in response to the demand from Europe for women physicians to take the place of men whose services have been required by their country and in this country for social work

Columbia Courses at Long Island College—Beginning with September, 1916, Columbia University will give, at the Long Island College Hospital, Brooklyn, a year of college work in physics, chemistry, biology, English, French and German This work is especially planned to enable prospective medical students to meet the admission requirements of the Long Island College Hospital The course will, however, be open and suitable for all, and those who take it will receive university credit

State Health Officer Wants Half a Million—State Commissioner of Health Biggs has appeared before the Government's Budget Committee to plead for an increase in the appropriation for his department The chief needs are the creation of a division for the prevention of tuberculosis the extension of laboratory work and the payment of full salary to sanitary supervisors The funds provided for the present fiscal year were not sufficient by $79,000 to pay the expert chemists engaged in blood tests and in the preparation of diphtheria antitoxin and other serums

Hospital of Rockefeller Institute—The Rockefeller Institute for Medical Research maintains a hospital in connection with its research work to which a limited number of patients is admitted According to a *Bulletin* just issued by this hospital, patients ill with acute lobar pneumonia, with diabetes mellitus, heart disease and nephritis are now admitted Physicians having such patients may communicate with the hospital No charge is made for treatment or other services Patients most acceptable at the present time are those cases of heart disease with broken compensation, especially those with edema, and cases of nephritis with severe symptoms and edema or those with threatened uremia

Radium Sanatorium Opened—An institution which occupies two private houses on West Seventieth Street is now open and receiving patients there being at the time of writing eighteen patients under treatment Already 300 milligrams of radium have been delivered to the institution and $130 000 worth has been contracted for The pathologic and biologic laboratories are being thoroughly equipped for the study of malignant conditions, and it is stated that all alterations in the building will be completed by January 1 There will be a dispensary for the treatment of outpatients The staff in surgery consists of Drs Cornelius G Coakley, John A Fordyce Charles H May, George D Stewart, Winfield Ayres, Henry C Coe Anthony Bassler, Eugene C Savidge George M MacKee William C Lusk Frederick E Sondern and Joseph B Bissell The medical staff of the institution has not yet been announced

Tuberculosis Week.—Since December 6 to 12 has been designated as National Tuberculosis Week, an effort will be made in this city to revive interest in tuberculosis, which is still the greatest public health problem The Department of Health will place emphasis on the importance of regular medical examinations Wednesday December 8 has been designated 'Medical Examination Day Hundreds of thousands of circulars are being distributed to the people of the city urging them to consult their family physicians and to submit to a thorough physical examination This effort of the Health Department is receiving the cooperation of the Charity Organization Society, the Tuberculosis Committee or the Brooklyn Bureau of Charities, the Metropolitan Life Insurance Company and the Prudential Life Insurance Company It is also suggested that physicians can render invaluable aid to the cause of public health by advocating regular medical examinations to their patients and by carrying out such examinations with care and thoroughness

Examination of Food Handlers by Private Physicians—Important changes have been made in connection with the examination of food handlers by private physicians Private physicians will be authorized to examine food handlers employed in kitchens and dining rooms of restaurants and hotels in compliance with the regulations of the board of health The physician desiring such authorization must make application to the department of health, and must observe the instructions of the department requiring that report blanks issued by the department of health be used, that a report card must be made out for each applicant, that all information asked for must be given, and an entry made in every blank space Because of lack of laboratory facilities the department of health is not yet prepared to demand a Widal test in every case, but a specimen for a Widal test must be forwarded in every instance in which the applicant gives a history of having had or having been exposed to typhoid fever A parole system has also been established for food handlers who are found to have a quiescent or arrested tuberculosis or a tertiary syphilitic condition without open lesion These applicants are given a short term certificate good for a period of one month and are required to present themselves at the end of that time, when on the recommendation of the examining physician, a renewal of the short term certificate for another month is given These advisory physicians give no treatment of any kind

PENNSYLVANIA

Personal.—Dr Edward S Dickey, Pittsburgh, will join Dr Esten L Hazlett, formerly of Pittsburgh, in Red Cross work at Tiflis, Russia

Health Exhibit Complimented—The state commissioner of health has received a telegram complimenting the Pennsylvania Health Department exhibit at the Panama-Pacific Exposition and asked that it be made a part of the government exhibit at the Panama National Health Exhibition which opens January 1

Communicable Diseases—The authorities of Jessup have ordered schools, churches, nickel shows and dance halls closed and have forbidden congregations of people on account of the prevalence of smallpox——The Walnut Street School, Hazleton, has been closed because of the existence of fourteen cases of diphtheria——On account of the prevalence of diphtheria in *Shamokin Dam, the schools* have been closed for fumigation

State Takes Charge of Borough Health Administration—Commissioner of Health Dixon on November 23 took charge of the public health administration of the boroughs of Jacksonville Hartleton Grand Valley, Curwensville, Meshoppen, New Buffalo Jefferson, Rice s Landing, Greensboro, Mt Morris, Finleyville Driftwood Cormont Hagerstown, Conneaut Lake, Venang Troutville, *New Washington,* Glen Hope Waterford Cranesville and Lockport This action was taken because the local boards of health were either inactive or not organized

Philadelphia

Favors Reconstruction of Hospital—Director Ziegler, of the Department of Health and Charities, favors the reconstruction of the Pennsylvania Hospital and endorsed the proposal of Senator James P McNichol which provides for an eventual expenditure of $8,000,000 in this work

Civil Service Examination—The civil service commission has scheduled for December 17 an examination for outdoor physician with an annual salary of $540 Applicants should call in person at the office of the commission, room 875, city hall, between 9 a m and 4 p m Applications must be executed and filed with the commission not later than three days prior to the day of the examination

Mutter Lecture—The Mütter lecture for 1915 will be delivered in the Thompson Hall, College of Physicians Twenty-Second Street above Chestnut on Friday, December 17, at 8 30 p m by Dr Rudolph Matas, professor of surgery in Tulane University, New Orleans, on "The Fundamental Principles that Underlie the Surgical Treatment of Aneurysm'——A reception will be given to Dr Rudolph Matas *New Orleans* at the Hotel Rittenhouse immediately after the Mutter lecture, December 17

Women Help City Hospitals—On November 30, Dr S Lewis Ziegler director of public health and charities appointed a 'Women's Advisory Council" to take charge of charity work at the Philadelphia General Hospital and the Philadelphia Hospital for Contagious Diseases The work of the council will be in line with the project for the establishment *of a greater hospital, the removal of the insane* from Blockley to Byberry and the removal of the indigent from the Blockley Alms House to Holmesburg

Personal.—Dr Andrew Anders was seriously injured in a collision between the automobile in which he was riding and a trolley car, November 29——Dr Douglas T Davidson of the staff of the University Hospital will sail from San Francisco early in January for China where he will become a member of the faculty of the medical *department of the* College of Changsha, Hunan Province, which is operated by Yale University Dr Davidson will be accompanied by his wife and two children——Dr John R Wells of the staff of the Pennsylvania Hospital and four nurses sailed from New York on the *La Touraine,* November 27, for France, where they will serve in the American Ambulance Hospital Neuilly——Dr Malcolm C Grow who left September 12 with Dr Edward H Egbert of Washington D C for Russia, was recently appointed chief surgeon with the rank of lieutenant-colonel on the twenty-first flying column of the Russian Red Cross under Commander Andrew Kalpashnikoff former secretary of the Russian Embassy at Washington——Dr Charles Bingham Penrose has been appointed a member of the Fairmount Park Commission to fill the unexpired term of Peter A. B Widener

CANADA

Personal—The Hon Dr Thomas S Sproule, Markdale, Ont, speaker of the Canadian House of Commons has been appointed a member of the Canadian senate——Dr George E Clerk, Melville Sask., has been appointed medical officer of the Sixty-Ninth Battalion, a French-Canadian battalion for overseas service

Medical Board at Camp Toronto—A medical board has been appointed to sit daily in *Toronto* in connection with sick soldiers in that divisional area This board consists of the following medical men Lieut-Col George Acheson Hamilton, Capt Albert H Rolph Toronto, Capt. Daniel A McClenahan, Hamilton

Hospital News—Fire broke out in the military hospital at Belleville, Ont, December 2 About 19,000 pounds of ammunition were stored in the building, but this and seven or eight patients were removed safely——A new Canadian hospital has been opened at Ramsgate, England, with accommodation for 600 patients Col Walter L Watt of Winnipeg is in charge——Lieut-Col Harry B Anderson and Lieut-Col Herbert A Bruce, Toronto, have been appointed to organize the Convalescent Home in Toronto for returned soldiers They will select the medical and surgical staffs at once, whose services will be gratuitous

Free Serums for Ontario—Following on the observations as to the results from the free use of diphtheria antitoxin in Toronto where the general death rate from diphtheria in that city is 16 against 6 in the Isolation Hospital where perhaps the worst cases are treated, the serum being supplied free to the hospital and in large doses, the Ontario government announces its intention to undertake, through the Ontario Board of Health, to supply free practically all the serums used in the province Of diphtheria antitoxin alone it is expected that from 150,000 to 200,000 doses will be required and about 500,000 doses for antityphoid innoculation The serums will be supplied free to physicians, hospitals, boards of health and the public generally Ontario is the first province in Canada to adopt this system of preventing communicable diseases and to lessen the incidence and death rate from those diseases

Ontario Medical Commission Resumes Sittings—Mr H S Osler, K C, Toronto, presented arguments before the Ontario Medical Commission last week, supporting the case for the Ontario College of Physicians and Surgeons, of which body he is counsel He first dealt with "patent medicines," pointing out that the public had no protection against the evils of many of these which were mostly foolish preparations Mr Justice Hodgins thought, however, that some of them were built on common-sense lines Mr Osler said in his understanding of the Ontario Medical Act any man who holds himself out as being competent to relieve suffering is practicing medicine, and in the "drugless healers" phase of his argument, said there should be some provision in the law to prevent unqualified people advertising themselves as "doctors" Mr Osler further stated that the College of Medicine and Surgery for Ontario was at one with all those who had appeared before his lordship pressing that a recognized university degree be the minimum standard of qualification He said doctors as a rule were not given to money making, and they were not prompted by any selfish motives in any effort they may make to have the act amended, it was solely in the public interest His lordship has asked the College of Physicians and the universities to confer and come to some common agreement as to what should be recommended He suggested that such a conference might take up the subject of fees charged by physicians as well as the fees charged for examinations Advertising on the part of any doctor might also be considered, in fact, what the commissioner desired was a full and complete statement of what in their opinion should be the status of the whole matter of medical education, examination and practice The commission sits in Hamilton the present week to hear the chiropractor society there It is understood Mr Justice Hodgins will investigate the college at Davenport for his own benefit

GENERAL

Western Surgeons to Meet—Surgeons from Baltimore to Butte are expected to be present at the meeting of the Western Surgical Association, which will hold its twenty-fifth annual meeting at the Chamberlain Hotel, Des Moines, December 17 and 18, under the presidency of Dr J Rilus Eastman, Indianapolis

First Aid Standardization—The Board on First Aid Standardization recently appointed by President Wilson, held its first meeting in Washington, November 27, and perfected its organization Dr Richard H Harte, Philadelphia, was elected chairman, and Asst Surg-Gen William Colby Rucker, U S P H S, secretary of the board

Alienists Elect Officers—At a meeting of the Interstate Psychiatric Association, held at the Sheppard and Enoch Pratt Hospital, Baltimore, November 23, the following officers were elected president, Dr Henry A Cotton, Trenton, N J, vice president, Dr Edward N Brush, Baltimore, and secretary, Dr Samuel T Orton, Philadelphia

Warning—Dr Hart Beyer, Pittsville, Wis, writes that during the latter part of July an agent called on him selling a vaporizing inhaler alleged to be manufactured in Philadelphia After writing to the address given, however, the letter was returned marked "not in directory," and on inquiry of the commercial agencies the firm named is not known

Opponents of Alcohol and Other Narcotics to Meet—The American Society for the Study of Alcohol and Other Narcotics will hold its forty-fifth annual meeting at the Hotel Raleigh, Washington, December 15 and 16 The public is cordially invited to be present, programs may be obtained from the secretary, Dr T D Crothers, Hartford, Conn

Typhus in Mexico—An Associated Press dispatch of December 4 states that typhus fever, which has been epidemic in and around the City of Mexico, has now increased to an alarming extent The death rate from this disease now exceeds 130 a day and is increasing It is estimated that there are at present 11,000 cases in the federal district and neighboring towns

Stock Plague Expensive—It is estimated that the direct loss due to the hoof and mouth disease epidemic in the United States, up to July 1, was $5,600,000 This estimate was made November 29 in a paper by A J Glover, Fort Atkinson, Wis, on "The Economic Effect of the Hoof and Mouth Disease," which was read before the conference of state and federal authorities in Chicago, November 29

National Examination Board Meets—The National Board of Medical Examiners closed its session at Raleigh Hotel, Washington, November 29, after adopting plans by which it is hoped that every state in the Union eventually will recognize its certificate from the National Board as sufficient credentials for the issue of a license to practice medicine The Medical Corps of three government services are represented on this board, of which Surg-Gen William Braisted, U S Navy, is president, and Col Louis A LaGarde, M C, U S Army, treasurer

Labor Legislation—The ninth annual convention of the American Society for Labor Legislation will be held in the Shoreham Hotel, Washington, December 28 and 29, and the program is to be devoted to vital questions of the day, the main topics being the Lafollette Law for the Protection of American Seamen, The New York Industrial Commission, A Practical Form of Health Insurance for Wage-Earners, and The Progress Made Throughout America in Industrial Hygiene, with Especial Reference to Dangerous Trades, Child Labor, Protection of Female Wage-Earners and The Factory Situation The closing meeting of the convention is to be held jointly with the Pan-American Scientific Congress, and the especial topic will be the "Progress Made in Industrial Hygiene in the Different Republics of the Two Americas"

Dogs as Carriers of Disease—The Department of Agriculture has issued a bulletin on dogs as carriers of disease Among the most interesting and important of these diseases at the present time is foot and mouth disease among cattle, of which, it is said, dogs act as mechanical carriers by running over infected farms Other maladies which may be spread by dogs are rabies, hydatid, ringworm, favus, tapeworm, round-worm, and tongue worm These may be conveyed to human beings Dogs may also be the carriers of fleas and ticks and by this means aid in spreading bubonic plague and spotted fever Dogs may become infected with various parasites by feeding on carrion and should be prevented from obtaining access to such material In outbreaks of ringworm or favus among children, the dog should be suspected as a possible source of the trouble

Stereopticon Loan Library—The U S Public Health Service announces that the service has established a stereopticon loan library, consisting of over 2,000 slides, the majority of which are original, dealing with public health problems These slides will be loaned without cost to physicians, health organizations, educators, welfare workers and others on application to the service They cover such subjects as Alaska, 83 views, children and children's diseases, 50 views, health exhibits, 90 slides, hookwork, 90 slides, Indians, 50 views, leprosy, 45 slides, living conditions, a small number, malaria, 275 views, milk, 80 views, mouth hygiene, 12 slides, parasites and organisms, over 200 views, pellagra, over 500 views, rural schools, 10 slides, service general, 320 slides, smallpox, 90 slides, trachoma, 120 slides, tropical diseases, 40 views, tuberculosis, 100 slides, typhoid fever, 350 views, yellow fever, many slides, as well as slides of other miscellaneous subjects These slides are 3½ by 4 inches and will fit most any lantern Catalogs of these views will be sent on request, out of which selections may be made, or the service will make the selections on any subject desired to be presented

Mental Hygiene Surveys—The National Committee for Mental Hygiene has completed surveys with reference to public and private provision for feebleminded, epileptics, insane and allied defectives, for Pennsylvania, South Carolina and Wisconsin Surveys are under way for Arkansas, Missouri, Texas and Florida State surveys will be undertaken for Maine, Rhode Island, Connecticut, New Jersey, North Carolina, Georgia, Tennessee, Indiana, Illinois, Kansas, Oklahoma, Washington, Oregon and California A map issued by the committee shows that separate provision for the feebleminded and the epileptic has been made in the following states Massachusetts, *Connecticut*, New York, Pennsylvania, Virginia, Ohio, Michigan, Indiana, Illinois Iowa, Kansas and Texas In Wisconsin Minnesota, South Dakota, Missouri, Oklahoma, Colorado, Wyoming, Washington, Oregon and California the feebleminded and epileptics are segregated from the insane, but are housed in the same institution Epileptics are not cared for by the state in states not mentioned. The following have no separate institutions for either feebleminded or epileptics Nevada, Utah, Arizona New Mexico,-Arkansas, Louisiana Mississippi, Tennessee, Alabama, Georgia, Florida, South Carolina and West Virginia

Examination for Medical Corps of the Navy—An examination for appointment in the Medical Corps of the Navy will be held on or about February 23 at Washington, D C., Boston, New York Philadelphia, Norfolk Va Charleston S C., Great Lakes (Chicago), Mare Island, Calif., and Puget Sound, Wash.

Applicants must be citizens of the United States and must submit satisfactory evidence of preliminary and medical examination The first stage of the examination is for appointment as assistant surgeon in the Medical Reserve Corps and embraces anatomy, physiology materia medica and therapeutics general medicine general surgery and obstetrics. The successful candidate must attend a course of instruction at the Naval Medical School which will begin on or about Oct. 1 1916 During this course he receives a salary of $2 000 per annum with allowance for quarters heat and light and at the end of the course, if he successfully passes examination in the subjects taught in the school he is commissioned assistant surgeon in the Navy to fill a vacancy Candidates must be between 21 and 30 years of age, graduates of a reputable school of medicine and must apply for permission to appear before a board of medical examiners The application must be in the handwriting of the applicant and accompanied by letters or certificates from two or more persons of good repute testifying from personal knowledge as to the good habits and moral habits of the applicant a certificate to the effect that the applicant is a citizen of the United States a certificate of preliminary education from an accepted high school or an accepted equivalent a certificate of medical education giving the name of the school and date of graduation and a certificate regarding hospital service or special education and professional advantages which the applicant has had

FOREIGN

Deaths Abroad—C Vincenti professor of hygiene at the University of Milan and founder and director of the *Corriere Sanitario* later changed to the *Avvenire Sanitario* aged 52——O Ughi, professor of pathology at the University of Parma

Octogenarian in the Field—A Berlin exchange states that his eighty-first birthday was recently celebrated by Dr Hertwig of that city now on active service with the troops at the front. This is his fourth military campaign, as he served in 1864, 1866, and in the Franco-Prussian war, and he is still well and active.

Extend Embargo Lists—In Denmark cotton goods and dried casein have been added to the list of products subject to embargo In France various food products, fruit, gum, mica, petrolatum and various types of sacks have been placed on the embargo list England has prohibited the exportation of cotton wadding, cotton wool and iron ore of all descriptions to all destinations

Hospital Factor for Peace—Baron Shibusewa, the Japanese financier at a luncheon given in his honor in New York by the American council of St Luke's International Hospital, Tokyo, said that the completion of the institution would prove a factor toward international peace The plans for the hospital were endorsed by the emperor, who had contributed $25 000 toward the fund The institution, he believed, would do much to bring closer relations between the United States and Japan

Bordeaux Exchange Resumes Publication—In November the *Journal de Médecine de Bordeaux* issued its first number since August, 1914 It is to be continued as a monthly This first issue contains a tribute to the twenty medical students at the University of Bordeaux who have fallen in the war It also lists the honors that have been conferred on members of the medical faculty and student body for conspicuous gallantry The leading and only original article is a clinical study of 330 cases of typhoid in soldiers

BERLIN LETTER

BERLIN, Nov 9, 1915

The War

TREATMENT OF WOUNDS IN WAR

In the sixth issue of "Military Surgery," published as a part of the *Beiträge zur klinischen Chirurgie*, Professor von Bruns discusses at great length the treatment of wounds received on the battlefield He says that the causes of shot wounds are entirely different in the present war from what they were in previous wars The wounds caused by artillery fire greatly outnumber the wounds caused by gun fire, being twice as numerous, whereas formerly they constituted from 5 to 25 per cent of all injuries Therefore, the number of large open wounds is also greater than the number of small bullet wounds Bullet wounds are practically never infected, whereas shrapnel and shell wounds are always infected primarily because of the large amount of tissue exposed, the nature of the wound, the tearing of the tissues, the time which necessarily must elapse between the infliction of the wound and the first-aid dressing, irrigation of the wound finger contact probing for bullets and tamponing The lack of sufficient immobilization of the injured part during transportation, especially in the case of bone and joint wounds, is also responsible for the production of infection The statement made years ago that the first-aid dressing practically determined the subsequent clinical course of the wound no longer holds true The primary wound infection is now the determining factor, and the results to be expected from our present knowledge of treatment of wounds are not realized English surgeons have stated that nearly all wounds with the exception of gun fire wounds, were infected and that no antiseptic could be depended on for a germicidal effect. Sir Almroth Wright has discarded the use of bandages, which, when saturated with wound secretion, favor the retention of septic products He recommends the use of a 50 per cent. salt solution with 0 5 per cent sodium citrate in the form of a bath, irrigation or compresses Under this treatment wounds apparently do very well in two or three days Another English surgeon, Sir Watson Cheyne, saturates wounds with pure phenol (carbolic acid) The thin layer of necrotic tissue which results from this treatment is absorbed The German war surgeons combat infection with the aid of the natural antibodies in the human body This is accomplished first of all by placing the injured tissue absolutely at rest immobilizing the extremities for bone and joint wounds If the infection increases in severity counter-openings are made Pieces of bone and foreign bodies are removed from the wound by irrigating with sterile salt *solution* When *suppuration* is present a moist dressing is applied, one that is not covered by rubber tissue, so that evaporation is furthered rather than prevented In very severe cases resort is had to the continuous bath or continuous irrigation Open wound treatment is also resorted to by some surgeons

REGULATING THE BERLIN MILK DISTRIBUTION

For the purpose of regulating the distribution of milk the Berlin authorities issue milk cards' which give the holder the privilege of being among the first to receive milk. Children under 6 years of age nursing mothers, and the sick and decrepit are given the preference Such persons are supplied with a "milk card" by the bread commission, and on presentation of this card to any milk dealer they are given first attention, but must call for this milk before a certain hour

ANTHROPOLOGIC INVESTIGATION OF PRISONERS OF WAR

The president of the Austrian Anthropological Society, Professor Toldt, and his students have examined 3,700 prisoners, making thousands of measurements This investigation has determined that among these people, as among other nationalities, there does not exist a pure race but only mixtures All of these people represent various racial elements which have been molded into one people by language and circumstances Even the Poles consist of five such groups In order to isolate these types, one must examine a large number of persons The type as such does not appear to be conveyed by heredity, but certain features of each type appear in the offspring To carry on such an investigation properly one must follow these racial characteristics geographically, for instance, in northwest Russia and extending through the country down to the Ural mountains are found the Finns, and coming from the east westward from the Ural mountains to the Volga, one finds the Mongolian races Among the former the prevailing type was that of the great Russian numbering 52,000 000 and resulting from a mixture of the Slav with the Finn, the German, the Tartar, etc There were three different types two blond and one brunette The little Russians, together with their relations in Galicia Bukovina and Hungary, number 32,000,000 The white Russians number only 3 500,000, and are said to speak the purest Russian dialect The Litauers and the Slavs in East Prussia number 32 000,000 They live in the governments of *Kowno and Wilma, and also in* Grodno and Suwalki They are said to speak the oldest of old Indo-Germanic tongues They are Catholics, but are strongly inclined to pagan practices

Alcohol and Crime

Speaking of the relationship of alcohol and crime in the Prussian statistics bearing on prisoners for 1913-1914 the president of the supreme district court, Mr Lindenberg, says Of the new male prisoners, 1,141, or 26 6 per cent (24 2 per cent in the previous year), committed the deed while intoxicated Among the female prisoners this percentage was considerably lower, 5 4 per cent Among the male prisoners 15 1 per cent, and among the female prisoners 12 per cent, were habitual drinkers

LONDON LETTER

London, Nov 19, 1915

Medical Research Under the Insurance Act

It may be remembered that under the national health insurance act an annual sum amounting to 2 cents for every insured person was granted for medical research In the year 1914 this amounted to $275,000 The outbreak of war has modified the scheme to some extent and temporarily, but *the main* idea stands Indeed, the war has afforded a fresh field of inquiry Thus at the outbreak of war it was determined to attack the many problems which were bound to arise on the field The services of Sir Almroth Wright were secured to investigate the bacteriology of wounds, with what results is already well known Sir Almroth's work, indeed, has been revolutionary Researches were also undertaken on the poisons producing gas gangrene, and on the nature of typhoid fever The work on antiseptics, in which many investigators have been engaged, has been assisted by the Research Committee The committee also sent Dr Freeman, of St Mary's Hospital, to Galicia in 1914 to investigate strains of cholera infection and to bring cultures to this country so *that if need* be—that is, if the disease spread—vaccines could be prepared The work of Lieutenant-Colonel Leiper, which has resulted in the discovery of the life history of the Egyptian bilharzia—a worm producing a disease which *has long* been regarded as one of the plagues of Egypt—was also assisted by the committee Lord Cromer, at the Royal Society of Medicine, characterized this work as of first-class importance to Egypt In the epidemic of cerebrospinal fever which lasted from January to June, much research work was accomplished Many of these researches have confirmed the fact that various conditions influence the virulence of bacteria, so that bacteria of the same type may show very different properties at different times Work is to be carried on to determine these factors *more precisely*, for it has often been suggested that on these epidemics other outbreaks of disease depend Other special researches include those on dysentery, industrial fatigue and the health of munition workers, the disorders of the soldier's heart, and gunshot wounds All this material will be made available in the official medical history of the war The peace plans of the committee were no less important, and they will, no doubt, be carried out at a later period They comprise investigations of such diseases as tuberculosis, rickets, diabetes, rheumatic infections, rheumatoid arthritis, oral sepsis and heart disease It is believed that the coordinating work of this committee marks the opening of a new era in medicine in this country which will differ from the old in that general statements founded on imperfect observation will be replaced by accurate knowledge gathered by careful and qualified observers in all the fields of medical work, correlated by competent statisticians, and presented in a form calculated to be of *lasting* value

Dr Charlton Bastian

Dr Henry Charlton Bastian, F R S, F R C P, has died at his residence, Chesham Bois He was educated at University College, London, where he was successively professor of pathologic anatomy, and professor of medicine In medicine he was principally interested in nervous diseases He was one of the brilliant galaxy which included Hughlings Jackson, Gowers *and* Ferrier, *who formed the staff of the* National Hospital for the Paralyzed and Epileptic, and created a British neurology His principal works, many of which were translated into other languages, were "The Brain as an Organ of Mind", "Paralyses Cerebral, Bulbar, and Spinal," and "Aphasia and Other Speech Defects," but it was by his work on the nature and origin of life that he was most widely known, because of the stoutness and persistence with which he maintained, contrary to all orthodox opinion, that life can arise from inorganic material He enclosed various materials in glass tubes, which he then sealed up and raised to temperatures of from 130 to 145 C for from five to twenty minutes According to all orthodox opinion, this should have killed every living thing in the tubes, yet on opening the tubes nine months later Dr Bastian declared that he found living micro-organisms His views were hotly contested from the moment when, in 1870, he first published *them* Huxley *and* Tyndall *entered* the arena against him, and even Pasteur was drawn into controversy Science accepted the arguments of Pasteur, and rejected those of Bastian Yet he did not lose heart, but continued to wage his fight to the end of his long life His first book on this subject, "The Beginnings of Life," was published as long ago as 1872 In 1904 appeared "Studies in Heterogenesis," in 1905 "Nature and Origin of Living Matter," and in 1907 "Evolution of Life" Only a few years *ago he had an* embittered *controversy* with *the Royal* Society, of which he was a fellow, because of its rejection of his Memoir "The Origin of Life," in which he once more with unabated vigor assailed the prevailing doctrines

The Protection of Patients in the London Hospitals Against Air Raids

The Zeppelin raids on London are a distinct danger to the patients in the numerous hospitals Indeed, more than one hospital had a narrow escape, being missed by only a few yards The problem of helpless patients unable to flee in case the hospital was set on fire by an incendiary bomb is a difficult and distressing one During the night when these raids occur the staff which remains on duty would be quite unable to remove the patients with sufficient speed All the great hospitals contain wounded soldiers in considerable numbers, and it was felt that it would be a reproach to London if any of these men, who had suffered so much already for their country, were to be burnt to death at home After the outbreak of war, volunteer corps consisting of men past the age eligible for the army (40 years) have been formed all over the country for home defense The idea occurred to one of these corps to provide *a detachment* of men each night at a large hospital which appears to be in a particularly dangerous situation, so as to be ready to remove the patients from any wing which might catch fire Their services were gladly accepted by the hospital authorities who made the following arrangement Each man is provided with an ash stretcher pole The patients are divided into three classes (*a*) those in bed who cannot walk or be carried, (*b*) those who can be carried on the back, or by bandy chair, (*c*) those who can walk The mattresses of the first group at all times have under them a canvas sheet with a wide hem on each side through which poles can be passed, thus forming a stretcher A supply of these sheets is provided in each ward, *and it* is the duty of the sister to see that one is placed under the mattress of every bed occupied by a patient who is too ill to be carried Each of these beds is indicated by a crimson tape, so that the stretcher-bearers will know at a glance which patient they have to remove on the improvised stretchers The third group will be directed and aided to leave the wards by the emergency staircases at the ends of the wings while the patients who have to be carried are being removed by the main staircase

Sanatogen Again

The eclipse of this fraudulent nostrum produced by the war is only partial Though all trading with Germany is prohibited there is nothing to prevent the stuff being produced in this country and exploited in the usual manner so long as none of the profits are sent to Germany However, the protection of the patent disappears for the time, and, as announced in a previous letter, a British company has taken advantage of the fact and produced an article called sanaphos, which it claims, is much better than sanatogen Sanatogen has just obtained a gratuitous advertisement by a question in Parliament as to whether a German alien enemy is carrying on the business and why he has not been interned The government reply was that the London business of the Sanatogen Company was now independently carried on in the interests of this country under a British supervisor appointed by the board of trade and any profits are paid over to the public trustee The case of the individual referred to was carefully considered who in view of the special circumstances, recommended that he should be exempted from internment on condition that a bond for $5 000 for his good behavior was entered into by two British sureties

PARIS LETTER

Paris, Nov 18, 1915

The War

TREATMENT OF HEAD WOUNDS FROM FIREARMS

This subject was discussed at length at the Reunion medicale de la VI-e armee, at which Dr Paul Mathieu of Paris reported fifty cases of this nature All the wounds were surgically explored no matter how insignificant the injury to the scalp seemed When the external surface of the skull was merely grazed the skull was opened up so that the condition of the inner side might be observed The dura mater was uncovered and incised in one case in which the skull was intact, but the patient had crises of localized epilepsy Twenty-seven other patients had lesions of the bone or of the brain and eight patients with osseous lesions without perforation of the dura mater all made an operative recovery The operation consisted of complete removal of fragments The existence under the intact dura mater of a hematoma or of a focus of cerebral contusion does not always necessitate incision of the dura mater, which may produce serious complications In cases of serious cerebral signs, however, evacuation of the subdural hematoma may be indicated It should be recognized that often patients with insufficiently drained wounds of the head have died in the base hospitals from late infectious complications Such patients should not be too early regarded as cured Permanent infirmities are frequent after wounds of the head Some patients retrogress completely others partially Neurologists should follow these patients for a long while.

Dr Ruotte emphasized the very great difference in the seriousness of wounds of the head in accordance with the involvement or noninvolvement of the dura mater When, during an operation, one finds a dura mater intact but tense and glistening the surgeon should consider opening it Ruotte thinks that in such cases simple puncture of the dura mater may give good results Trephining is specifically indicated if one finds the least cranial lesion, even the most superficial If it is merely a scratch of the external surface of the skull, trephining should always be employed Dr Reverchon has had occasion since the beginning of the war to trephine 100 times He finds that wounds of the scalp should always be explored with the greatest care, and that often trephining, where there is a very slight wound of the external surface, enables the surgeon to find lesions that might have been overlooked In cases of hematoma of the dura mater the great danger of systematic incision is infection Therefore, as Ruotte says, there is much reason to use simple puncture in these cases Reverchon punctured the dura mater not with a Tuffier needle which would be unsatisfactory, but with the point of the bistoury When the dura mater presents a wound from fragments of bone or projectile it should be opened up, but this operation is followed by cure only if it is done under conditions of scrupulous asepsis Patients with wounds of the dura mater should not be operated on in ambulances of the first line They should be taken to the rear and operated on only in a place where perfectly aseptic surgery is possible

LABARRAQUE'S SOLUTION AND DAKIN'S SOLUTION

At a recent session of the Societe de chirurgie de Paris, Dr Pierre Delbet professor in the surgical clinic at the Faculte de medecine de Paris called attention to the fact, already mentioned in The Journal (Sept 4, 1915 p 889) that Labarraque's solution and the antiseptic solution of Dakin are obtained by the same process The solution of sodium hypochlorite of the French Codex or Labarraque's solution is obtained by double decomposition of calcium hypochlorite (the chlorid of lime of commerce) and sodium carbonate, the calcium, united to the carbonic acid, is precipitated and the sodium hypochlorite remains in solution with the excess of sodium carbonate The antiseptic solution of Dakin is obtained in the same way, but to the concentrated sodium hypochlorite resulting from the double decomposition is added a certain quantity of boric acid which principally neutralizes *the original alkalinity of the solution* The long-known favorable effect of the hypochlorite solutions of commerce should be attributed to their irritant action on the tissues The treatment to which Dakin subjects the hypochlorite solutions in order to lessen their irritant effect can only diminish their efficacy in the treatment of wounds This is demonstrated every day

Professor Qenu believes that Delbet is right in calling attention to the irritating effect which certain chemical substances have on wounds The antiseptic may be useful in fact, not only because it does not destroy the living cells, but also because it excites their vitality causes the proliferation of the leukocytes and consequently hastens the elimination of elements altered by traumatism and microbes or their toxins

EXTRACTION OF BULLETS FROM THE BLADDER BY THE NATURAL CHANNELS

At a recent session of the Academie de medecine de Paris, Dr F Legueu, professor of the clinic of diseases of the urinary tract at the Faculte de médecine de Paris, read an interesting paper on this subject. Rifle shot and grape shot are of such size and shape that they may be easily and rapidly removed through the urethra without incision For this purpose Legueu uses a special lithotrite modified for the purpose. The instrument, introduced into the bladder by the urethra, seizes the ball by its point on touching it and in less than a minute the extraction is made without anesthesia One patient left the hospital the next day A superior officer who had been unable to walk for eight months was soon enabled to resume his duties The most difficult thing is to ascertain that the ball is actually in the bladder in cases in which it comes from a very distant part of the body and is embedded in the tissues during the whole of the cicatrization of the wound When radiography shows a pelvic ball two successive plates should be made, changing the patient's position If the ball shifts its place, this shows that it is in the bladder Only balls that are free in the vesical cavity can thus change their position. Cystoscopy, however, is the most useful method of exploration for giving an idea of the presence, the situation, the mobility of the ball, the condition of its surface and all the data necessary for the extraction by the natural passage, which remains the best and most expeditious method.

RELIEF OF PHYSICIANS AT THE FRONT

I mentioned in a previous letter (The Journal, Nov 20, 1915 p 1831) that the minister of war had decided that physicians at the rear who had not yet taken their place in the armies should replace their comrades fatigued by fifteen months of campaign Out of over 8,000 physicians at the front, only 1,500 have asked for relief on this ground but there are no more than about 600 of these physicians fit for service who have not been at the front The time set for each physician's departure is determined by his age and by his service in the army The exchange is made regularly but not too frequently, so that there is not likely to be any disorganization which might affect the patients unfavorably

THE FRENCH WOUNDED EMERGENCY FUND

The undersecretary of the military medical service has just decided to accept the aid of the French Wounded Emergency fund, an Anglo-American society the delegate of which in

France is Mrs Hendry, nee Charcot The purpose of the society is to distribute in the various hospitals which receive patients from the army gifts for the improvement of the condition of the soldiers The under secretary has therefore authorized Mrs Hendry and fifteen of her collaborators to cooperate with the head physicians of the hospitals in distributing such gifts

MEMORIAL TO DR. REYMOND

The general council of the department of the Seine and the prefect of police have placed in the surgical operating room at Nanterre the bust of Dr Emile Reymond, who was a senator and surgeon of this establishment and who died bravely in an aviation reconnaissance of the army (The Journal, Nov 21, p 1868) The bust is the work of the sculptor Gauquie The president of the republic and other high officials were represented at this ceremony Several speeches were made recounting the career and the glorious death of Dr Reymond

THE WAR AND THE STATISTICS OF POPULATION OF FRANCE IN 1914

The *Journal officiel* has just published the statistics of population of France in 1914 Ten French departments are still, in whole or in part, under invasion The figures, therefore, apply to only seventy-seven departments instead of eighty-seven, and are also incomplete with regard to deaths during the first five months of hostilities

The following are the figures

1 The number of deaths is provisionally estimated at 647 549 an increase of 58 740 over 1913 (588 809)

2 The number of births is estimated at 594,222, a decrease of 10,232 from 1913 (604,454)

3 The excess of deaths over births was 53,327 This indicates that the population of France diminished last year by 53,327 In 1913 there was an insignificant increase of 15,645

4 The number of marriages was 169,011, a decrease of 78 742 from 1913 (247,753)

5 The number of divorces was 7,884, a decrease of 4,460 from 1913 (12,344)

To estimate the influence exercised by war on the status of the population, it is interesting to compare the changes in population in seventy-seven departments during the last semester of 1913 and the corresponding semester of 1914

1 During the second semester of 1914 the number of deaths recorded was 323,018, as against 280,804 during the corresponding period of 1913, an increase of 42,214

2 The number of births diminished from the one year to the other by 6,676 (300,304 in the second semester of 1913 and 293,628 in the second semester of 1914)

3 The number of marriages decreased by 65 per cent 43,585 in the second semester of 1914 against 122,754 in the second semester of 1913

4 The number of divorces diminished from 6,307 to 2,014

5 The number of illegitimate children increased by more than 2,000 19,798 in 1914 against 17,684 in 1913

NERVOUS AFFECTIONS CAUSED BY BURSTING OF SHELLS IN THE PATIENT'S VICINITY

At a recent session of the Reunion medico-chirurgicale de la X-e armee, Drs Gustave Russy and J Boisseau read an interesting paper on this subject, based on sixty-seven cases of nervous affections provoked by bombardment The conditions in which these disturbances occur are always the same bursting of a shell of large caliber near by, killing or wounding neighboring comrades more or less prolonged loss of consciousness, followed by an outbreak of nervous disturbances The latter may be grouped in three classes

1 Disturbances of hearing and speech (deafness, loss of speech, deafmutism, stammering) The patients sometimes present an expression of terror and mental confusion, sometimes an impassive and stupefied countenance, sometimes an expressive mimicry, gesticulating, pointing to their ears, demanding to write

2 Various nervous complications such as trembling, convulsive crises astasia, paraplegia etc

3 Mental disturbances such as confusion with stupor and delirious ideas

Somatic signs sometimes observed are a very slight and temporary elevation of temperature with often persistent headache In eleven out of sixteen cases of deafness, examination revealed the presence of small lesions, generally old, sometimes recent In seventeen out of nineteen cases examination of the cerebrospinal fluid gave negative results (generally the fluid trickled drop by drop, there was no hyperalbuminosis or lymphocytosis), in two cases there were positive results (slight hyperalbuminosis in one, slight lymphocytosis in the other) The two patients presented mental confusion and the second had albuminuria

Cure always followed the treatment, immediately (that is, within a day), or tardily (within two or three days in the intense forms)

The complications presented in the sixty-seven cases could all be classified as functional or hysterotraumatic There are no signs which give reason to suspect a disturbance of the central nervous system, no reflex trouble, no chemical or cytologic modification of the cerebrospinal fluid All the symptoms disappeared very rapidly under suggestion The ease and rapidity of cure of these patients treated at a date very near the onset of the condition contrasts singularly with the slowness and even the failures observed in the zone of the interior There would appear to be considerable practical value in early treatment from the military point of view

LOCALIZED TETANUS

At a recent session of the Academie de medecine de Paris, Professor Pozzi reported a case of parapVegiform tetanus localized in the lower limbs and appearing early (five days after the wound) following a serious wound of the left foot from a fragment of shell necessitating submalleolar amputation Extremely painful spasms, at first clonic, then tonic, remained localized in the left leg and thigh with a temporary irradiation to the right leg depriving the patient of all rest and sleep The temperature, very high at first, fell after the operation, performed the tenth day The stump healed normally and the general condition became very good but the contracture of the left leg continued The treatment consisted in strong doses of bromids, chloral or other sedatives, as well as massive doses of antitetanic serum Great improvement resulted The convulsions ceased but the contracture persisted, holding the leg strongly flexed on the thigh The prognosis is good but it is to be feared that the stiffness and flexure of the leg will continue for a long time

Cases of partial or localized tetanus are very rare A form of delayed cephalic tetanus is well known, but cases of tetanus localized in a single limb, or monoplegia, are quite unusual up to the present In a recent thesis Ramirez-Martinez was able to collect only two observations Both were cases of wounds of the foot The appearance of tetanus was very much delayed (three months for one and fifteen days for the other) The observation of Pozzi is the first case in which incubation was so short (five days) It is therefore a case of precocious localized tetanus, and also the first case of partial paraplegiform tetanus

---

Marriages

George Lauman Laverty, M D, Harrisburg, Pa, to Miss Rebekah Eleanor Kendig of Roland Park, Md, November 20

Ralph Hiram Knapp, M D, Youngsville, Pa, to Miss Margaret I Johnston of Clinton, Mass, September 1

Guy Edward Campbell, M D, Plentywood, Mont, to Miss Helen Collins of Barnesville, Minn, November 10

Henry L Schelling, M D, Brooklyn, to Mrs Isabel Hanson Woodford of New York City, November 23

Clarence Gilbert Goodwin, M D, Chicago, to Mrs Minnie Starr Grainger of Belvidere, Ill, November 24

Joseph Anthony Stockler, M D, Reading, Pa, to Miss Ellen McKeon of Newark, Del, November 27

Seavy Highsmith, M D, Fayetteville, N C, to Miss Ethel Johnson of Red Springs, N C, November 23

Joseph Aloysius Henske, M D, to Miss Kathryne McClanahan, both of Omaha, November 3

Sherman Grant Bonney, M D, Denver, to Mrs Jessie Ellwood Ray, in St Louis, December 1

George Warren Thompson, M D, to Mrs Julia Williams, both of Winamac, Ind, November 25

Joseph H Bloomer, M D, to Mrs Idella M McDavitt both of Quincy, Ill, November 17

Roy Brown Seely, M D, to Miss Emma Gissel, both of Brooklyn, August 4

Deaths

Frederick William Russell, M D New York University, New York City 1870, aged 70, a member of the Massachusetts Medical Society, hospital steward, U S V during the Civil War, formerly physician to the Children's Hospital, Baldwinsville and vice president of the institution, chairman of the Board of Health of Winchendon Mass, and proprietor of The Highlands Sanitarium, Winchendon, eminent as an entomologist and a member of the American Entomological Society, for the last three years a resident of Dallas Texas, honorary president of the Texas Harvard Club and an honorary member of the Dallas Medical and Surgical Association, died at the home of his daughter in that city, November 20

George Reuling, M D University of Giessen, Germany 1866, aged 76, formerly assistant to Dr Pagenstecher of Weisbaden Germany, a practitioner of Baltimore since 1868 one of the founders of the Eye and Ear Hospital as an adjunct of the Maryland General Hospital, a pioneer in operative surgery of the eye and ear, lecturer at a number of medical schools in Baltimore and professor and later emeritus professor of ophthalmology and otology in Baltimore Medical College, ophthalmologist on the staff of the German Hospital, of late years an art connoisseur, died in the Maryland General Hospital November 25, from rheumatic endocarditis

Edward Cummings, M D Medical College of Virginia Richmond 1903 aged 44, a Fellow of the American Medical Association assistant surgeon to the Hinton (W Va) Hospital and bacteriologist to the Chesapeake and Ohio Railway at one time city editor of the *Daily Journal and Tribune* of Knoxville Tenn , a veteran of the Spanish-American War, a prolific writer on tuberculosis to the study and treatment of which he had devoted the last years of his life, died at his home in Hinton, W Va November 25, from pulmonary hemorrhage.

John C Hutton, M D University of Pennsylvania, Philadelphia, 1867, aged 69, first health officer of Harrisburg, Pa , for many years president of the City Board of Health and a member of the staff of the City Hospital, founded the Municipal Hospital for Contagious Diseases, for two terms a member of the board of education and for three years a member of the common council of Harrisburg died at his home in Elkwood New Cumberland Pa., November 20

Henry McKee Tucker, M D University of Maryland Baltimore, 1899, aged 40, of Raleigh, N C , a member and formerly treasurer of the Medical Society of the State of North Carolina, professor of obstetrics in the University of North Carolina and of gynecology in Leonard Medical School, Raleigh, who underwent operation for mastoiditis at Rex Hospital, Raleigh on November 22, died from a secondary meningitis November 24

Benjamin Joy Jeffries, M D Harvard Medical School 1867, aged 82, a member of the Massachusetts Medical Society and American Ophthalmological Society, formerly consulting ophthalmic surgeon to the Massachusetts Charitable Eye and Ear Infirmary State Hospital and New England Hospital for Women and Children, author of Color Blindness Its Dangers and Detection", died at his home in Boston, November 21

Andrew J Martin, M D University of Buffalo, N Y., 1887, aged 55 a Fellow of the American Medical Association and a well-known practitioner of North Tonawanda N Y , a member of the Board of Health and health officer for several years, coroner of Niagara County for three years, died in the German Deaconess Hospital Buffalo November 24, five days after an operation for disease of the intestines

Fayette Kent Waller, M D Miami Medical College, Cincinnati 1878, aged 68, a veteran of the Civil War, and for many years a practitioner of Wabash, Calhoun and Madison counties Ill , who had been an inmate of the Odd Fellows Home Mattoon, Ill, for seven years, died in that institution November 19, from cerebral hemorrhage

William F Ham, M D College of Physicians and Surgeons, Keokuk, Iowa, 1864 Rush Medical College, 1868, aged 72 surgeon of the One Hundred and Seventy-Second Ohio Volunteer Infantry during the Civil War and afterward a practitioner of Middlebury Ind , died at the Soldiers' Home near Lafayette Ind., November 23

William Frisbie Lewis, M D College of Physicians and Surgeons in the City of New York, 1854, aged 85, for many years a practitioner, druggist and banker of Mankato, Minn , a veteran of the Indian War of 1857, since 1887 a resident of California, died at his home in Palo Alto, Calif, November 18 from senile debility

Frederick W Messerve, M D Hahnemann Medical College, Philadelphia, 1885, aged 55, for many years resident physician at Hahnemann Hospital, Philadelphia, professor of ophthalmology in his alma mater and ophthalmologist to various hospitals in Philadelphia, died at his home in Berlin, N J, November 22

Thomas Ayars James, M D New York University, New York City, 1880 aged 65, a Fellow of the American Medical Association and president of the Luzerne County (Pa) Medical Society in 1885 one of the best known practitioners of the Wyoming Valley died at his home in Ashley, November 10, from heart disease

LeRoy R Craig, M D University of Louisville, Ky., 1895, aged 41, a member of the Nebraska State Medical Association, for several terms coroner of Scotts Bluff County, Neb and county health officer and a member of the Board of Health of Mitchell, died at his home in Mitchell, November 24, from heart disease

Elfred Rowe Barney, M D University of Michigan, Ann Arbor 1872, aged 64 a Fellow of the American Medical Association, for twenty one years a practitioner of Wattsburg Pa for twenty years a member of the local school board and for twelve years its president, died at his home, November 17

Daniel Berry, M D Jefferson Medical College, 1866, aged 80 a veteran of the Civil War in which he served as assistant surgeon of the Eighty-Seventh Illinois Volunteer Infantry later a practitioner and druggist of Carmi, Ill died at his home in that city November 19, from cerebral hemorrhage

J Clayton Alexander, M D Chicago College of Medicine and Surgery 1907 aged 48 formerly a Fellow of the American Medical Association, of Hope, N D was injured by the overturning of his automobile about 4 miles south of Hope, November 6 and died at his home five hours after the accident

John T Kennedy, M D College of Physicians and Surgeons in the City of New York 1861, aged 75, for nearly half a century a practitioner of New York City, for eighteen years chief surgeon to the New York Hospital, died in his apartments in New York City, November 26, from heart disease

Godfrey J D Hindley University of Oxford, England, 1892, L.R C P, London M R C S, England 1897, aged 43, formerly a practitioner of Carpinteria, Calif, and of Hilo, Hawaii, was lost at sea at the Dardanelles, early in September, by the sinking of a transport on which he was on duty

John Ezra King, M D State University of Iowa, Iowa City 1897, aged 50, formerly a Fellow of the American Medical Association, died at his home in Anamosa, Iowa, from the effects of cyanid of potassium believed to have been self-administered with suicidal intent, while of unsound mind

Arthur Irving McCumber, M D Rush Medical College, 1905, aged 38, of Lewiston, Ill , a patient at the Wilgus Sanitarium, Rockford, on account of nervous breakdown, threw himself under an interurban car about a mile from Rockford, November 20, and was instantly killed

George Moses Hawkins (license Kansas 1901), aged 78, a practitioner since 1857, surgeon of the Tenth Pennsylvania Volunteer Cavalry during the Civil War, formerly a member of the Kansas Medical Society, died at his home in Dexter, Kan , October 2, from cerebral hemorrhage

Samuel Morrow Crawford, M D University of Pennsylvania Philadelphia, 1878 aged 63 a member of the Medical Society of the State of Pennsylvania, for eleven years chief medical inspector of the Pennsylvania System in Harrisburg, Pa , died at his home in that city November 20

William Hambleton Tolson, M D Baltimore University School of Medicine 1890 for several years director of the academic department of the Maryland State Normal School and later principal of No 80 Public School, Baltimore, died at his home in Baltimore, November 24

Cornelius Joseph O'Neil, M D Western Pennsylvania Medical College, Pittsburgh, 1900 aged 40, chief medical examiner in the Pittsburgh Department of Charities and for twelve years school physician, died at his home in Pittsburgh, November 25

William Henry Gesner Griffith, M D Hahnemann Medical College, Philadelphia, 1872, aged 82, assistant surgeon of Volunteers during the Civil War, one of the founders of the McKinley Hospital, died at the home of his son in Trenton, N J, November 24

Daniel Tufte, M D University of King Frederick, Christiania, Norway, 1893, of Pelican Rapids, Minn, who was studying in Germany at the outbreak of the European war and joined the medical staff of the German army, died in Germany, November 10

George Edwin Pinkham, M D Dartmouth Medical School, Hanover, N H, 1863, aged 75, a member of the Massachusetts Medical Society, assistant surgeon of Volunteers during the Civil War, died at his home in Lowell, Mass, November 15

Henry Philips Hirshfield, M D University of Pennsylvania, Philadelphia, 1878, aged 61, a member of the Medical Association of the State of Alabama, coroner of Mobile County for twenty-one years, died in the Inge-Bondurant Sanatorium, Mobile, November 14

George Henry Charles Klie, M D Missouri Medical College, St Louis, 1895, aged 70, a Fellow of the American Medical Association and a well-known practitioner of St Louis, died in the St Louis Mullanphy Hospital, September 24, from carcinoma of the stomach

William A Garner, M D College of Physicians and Surgeons, Keokuk, Ia, 1885, aged 55, a Fellow of the American Medical Association, local surgeon of the Wabash System at Clayton, Ill, died at his home in Clayton, November 14, from organic heart disease

Edward L Stewart, M D Vanderbilt University, Nashville, Tenn, 1891, aged 47, of Tampa, Fla, a specialist on diseases of the eye, ear, nose and throat, formerly health officer of Tampa, is said to have committed suicide in Tampa, November 11

John P Dunnigan, M D Georgetown University, Washington, D C, 1901, aged 41, a Fellow of the American Medical Association and a member of the surgical staff of Providence Hospital, Washington, D C, died in that institution, November 11

Robert Davis Webb, M D Medico-Chirurgical College of Philadelphia, 1893, aged 44, of Philadelphia, died in St. Joseph's Hospital in that city, November 13, from fracture of the skull believed to have been accidentally sustained as the result of a fall

John Calvin Webster, M D Harvard Medical School, 1867, aged 72, a member of the Illinois State Medical Society, a veteran of the Civil War, for forty-eight years a practitioner of Chicago, died at his home in Chicago, November 15

C Anton Holzer, M D University of Strassburg, Germany, 1878, aged 67, a practitioner and pharmacist of Uniontown, Wash, for several terms a member of the city council and mayor for one term, died at his home in Uniontown, November 12

David S Tate, M D Chattanooga, Tenn, Medical College, 1900, aged 50, a well-known practitioner of South Pittsburg, Tenn, died in the Newell Infirmary, Chattanooga, Tenn, October 2, after an operation for disease of the intestines

Isaac Newton Kelly, M D Louisville, Ky, Medical College, 1907, aged 32, formerly a Fellow of the American Medical Association and a physician in the United States Indian Service, died in Garfield, Wash, November 8, from nephritis

Robert A. Chambers, M D Tulane University, New Orleans, 1892, aged 48, for fourteen years a resident of Columbus, Ga, died in the Columbus City Hospital, November 11, from peritonitis following an operation for appendicitis

Adolf Decker, M D University of Wurzburg, Germany, 1881, aged 56, at one time president of the German Medical Association, Chicago, noted as a chess player and composer of chess problems, died at his home in Chicago, November 20

Charles A Fox, M D Medical College of Virginia, Richmond, 1868, aged 72, a Confederate veteran and for fifty-two years a practitioner of Beltsville, Md, died at the home of his daughter in Washington, D C, November 13

John F Kanawel, M D University of Pennsylvania, Philadelphia, 1879, aged 80, a member of the Medical Society of the State of Pennsylvania, died at his home in Penn's Creek, Pa, November 1[illegible], from cerebral hemorrhage

George H Peck, M D Detroit Homeopathic Medical College, Detroit, Mich, 1873, aged 77, for several years health officer of New Philadelphia, O, died at his home in New Philadelphia, November 15, from arteriosclerosis

Robert L Morrison, M D College of Physicians and Surgeons of Kansas City, Kan, 1904, aged 37, a member of the Oklahoma State Medical Association, died at his home in Poteau, November 15, from nephritis

William C Q Wilson, M D Starling Medical College, Columbus, Ohio, 1872, aged 66, formerly a member of the West Virginia State Medical Association, died at his home in Mannington, W Va, November 14

John Hockenhull, M D Medical College of Georgia, Augusta, 1855, aged 83, a Confederate veteran, for many years a practitioner and druggist of Cumming, Ga, died at his home in that place, November 12

Simeon J Zabriskie, M D New York University, New York City, 1856, a member of the Medical Society of the State of New York, died at his home in Westwood, N J, September 11, from senile debility

William C Day, M D Missouri Medical College, St Louis, 1861, aged 78, emeritus professor of obstetrics in the American Medical College, St. Louis, died at his home in White Hall, Ill, November 13

R A Turner (license Texas, 1907), aged 34, of Lovelady, Tex., was found dead in the Cadillac Hotel, November 14, from the effects of chloroform believed to have been accidentally self-administered

Orren Stoddard, M D Medical College of Indiana, Indianapolis, 1886, aged 72, a veteran of the Civil War and for thirty years a practitioner of Merom, Ind., died in Indianapolis, November 12

Philo Anderson Lutz, M D College of Physicians and Surgeons, Baltimore, Md, 1886, aged 55, formerly of Harrisburg, Pa, died at his home in Baltimore, November 12, from heart disease.

Horace Besson Heysham, M D Jefferson Medical College, 1900, aged 42, formerly resident physician to the Charity Hospital, Norristown, Pa, died at his home in Norristown, November 16

Joseph M Craig, M D New Orleans School of Medicine, 1861, aged 84, major surgeon in the Confederate service during the Civil War, died at his home in Amite, La, November 15

William Moor Pulsifer, M D Harvard Medical School, 1886, Hahnemann Medical College, Philadelphia, 1887, aged 52, died at his home in Skowhegan, Me, October 31

William Elvin Pritchard, M D Chicago Homeopathic Medical College, 1886, aged 56, died at his home in Los Angeles, November 14, from cerebral hemorrhage

Joseph D Tuthill, M D Bennett Medical College, Chicago, 1881, aged 87, a practitioner for more than sixty years, died at his home in Chicago, November 26

William C Yolton, M D Western Reserve University, Cleveland, 1887, aged 68, died at his home in Frankfort Springs, Pa, November 12, from pneumonia

Charles C Pierson, M D University of Louisville, Ky, 1907, aged 37, of Kiefer, Okla, died at the home of his mother near New London, Ia, November 15

J M C King (license, Twenty-Seventh Judicial District Board, Texas, 1880), aged 63, died at his home in Merkel, Tex, August 26, from diabetes

Edwin Forrest Philips, M D Jefferson Medical College, 1871, aged 66, died at his home in Tower City, Pa, November 17, from pneumonia

Herman C Block, M D Chicago Homeopathic Medical College, 1885, aged 63, died at his home in Milwaukee, Wis, November 10

Henry Clay Stone, M D Louisville, Ky, Medical College, 1892, aged 70, died at his home in Constantine, Ky, November 11

Levi Ormsby Johnson, M D University of Michigan, Ann Arbor, 1868, aged 74, died at his home in Chicago, November 15

John Henry DeWitt, M D Jefferson Medical College, 1880, aged 60, died at his home in Philadelphia, November 14

John W Fawdrey, M D New York Homeopathic Medical College, 1892, died at his home in Corfu, N Y, November 10

Robert F Taylor, M D Pulte Medical College, Cincinnati, 1877, aged 66, died at his home in Napa, Calif, November 8

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

THE HOME HEALTH CLUB

David H Reeder's Ingenious Scheme for Advertising "Patent Medicines"

The medical mail-order faker's most valuable asset is his mailing list and obtaining this list is his greatest item of expense David H Reeder one time of Laporte, Ind, but now of Chicago, has solved the problem in a way which makes up in ingenuity what it lacks in honesty David H Reeder is the president and apparently chief owner, of the Home Remedies Company," originally of Laporte Ind, now at Cottage Grove Avenue, opposite Fiftieth Place, Chicago" The company is a 'patent medicine" concern that sells its remedies on the mail-order plan The Home Health Club" has its headquarters with the Home Remedies Company but advertises its address as "5039 Cottage Grove Avenue, Chicago' The 'founder' of the Home Health Club and the author of the 'Club Books and Lectures is David H Reeder

TRADE MARK

Some letterheads of the Home Health Club and the Home Remedies Company when these were operated at Laporte Ind Dr David H Reeder calls himself founder of the 'club and he is president of the patent medicine concern

Reeder[1] poses—in print—as a physician A careful search of all available records, and they are extensive, fails to show that Reeder ever was graduated by a medical college or ever was granted a license to practice medicine by any state In the past, Reeder has not hesitated to put "M D' after his name, more recently he has become wary Volume I of the Home Health Club was written according to the title page, by David H Reeder, M D, Ph D", Volume III of the Home Health Club had for its author, according to the title page David H Reeder, D O., Ph D"

Reeder's business is the selling of (1) alleged health books (with a 'Certificate of Membership' in the Home Health Club thrown in) and (2) "patent medicines,' both on the mail-order plan Reeder has worked out a novel idea for getting his customers He has eliminated the chief item of 'overhead expense' usually inseparable from the mail-order business, that of paying for advertising space His scheme is to write to certain newspapers offering to furnish free "copy" for a "Health Department," to be conducted under the title "Home Health Club" To allay the suspicions that would, naturally, arise in the minds of those editors to whom such an offer came, the Home Health Club explains how it is able to furnish free "copy" for the newspaper It asks that the 'service" offered be given credit to the club "by name and address" Continuing, the letter to the editor says

> 'Through this publicity inquiries are brought directly to the club which promotes the sale of the books compiled and reprinted from the lectures in various papers to which they are furnished These sales amply cover the expenses of the organization which explains how the club is enabled to provide you the matter free."

Notice that no reference is made to the patent medicine" side of the enterprise The sale of books alone is given as the excuse for furnishing free 'lectures"

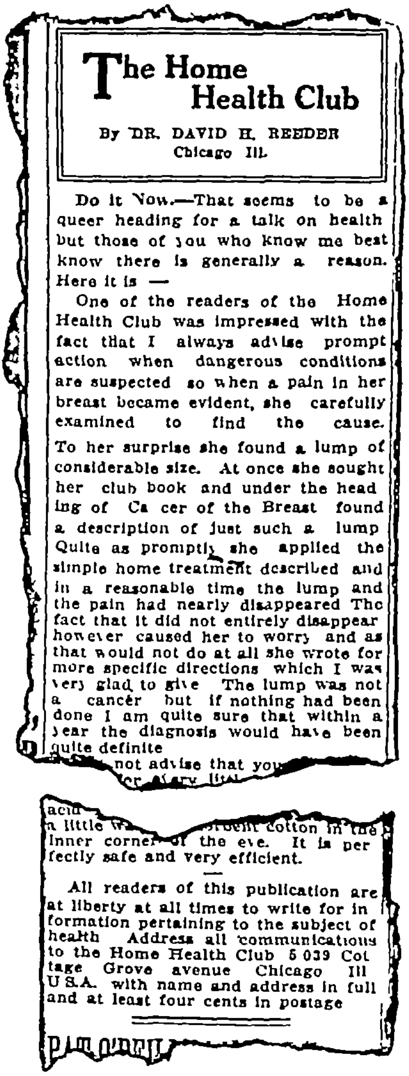
HOW IT WORKS

The way in which Reeder's scheme works out may best be explained by detailing some specific cases A young woman wrote to Reeder giving no details but stating that she was 'weak and run down" and asking for advice Reeder replied in a letter replete with platitudes regarding diet and exercise and suggested that the girl purchase 'Home Health Club Book Vol 1' price $1 and carefully observe the directions given therein For a tonic Reeder recommended Re-New-U' which he declared, is excellent"

> Its influence upon the stomach the liver the bowels and the kidneys as well as heart is the very best and I believe that it will be just the thing for you to take. It is sold under the name of Re New U by the Home Remedies Company at the price of $0 50 per box $2 50 for six boxes.

Enclosed with the letter containing these recommendations was a descriptive price list of the Home Health Club publications The correspondent was told that every purchaser of Volume 1 receives a Certificate of Corresponding Life Membership" The day following the receipt of this letter and advertising brought the young woman a letter from the Home Remedies Company

It is worth noting here, that Reeder carefully avoids letting the public know that there is any connection between the Home Health Club and the Home Remedies Company The Home Health Club's address is always given 5039 Cottage Grove Avenue, Chicago,' while the advertising matter of the Home Remedies Company bears the address 'Cottage Grove Avenue, opp Fiftieth Place.'



The Home Health Club

By DR. DAVID H. REEDER
Chicago Ill.

Do it Now.—That seems to be a queer heading for a talk on health but those of you who know me best know there is generally a reason. Here it is —

One of the readers of the Home Health Club was impressed with the fact that I always advise prompt action when dangerous conditions are suspected so when a pain in her breast became evident, she carefully examined to find the cause.

To her surprise she found a lump of considerable size. At once she sought her club book and under the heading of Ca cer of the Breast found a description of just such a lump Quite as promptly she applied the simple home treatment described and in a reasonable time the lump and the pain had nearly disappeared The fact that it did not entirely disappear however caused her to worry and as that would not do at all she wrote for more specific directions which I was very glad to give The lump was not a cancer but if nothing had been done I am quite sure that within a year the diagnosis would have been quite definite

not advise that you

acid

a little cotton in the inner corner of the eye. It is perfectly safe and very efficient.

All readers of this publication are at liberty at all times to write for information pertaining to the subject of health Address all communications to the Home Health Club 5 039 Cottage Grove avenue Chicago Ill U S.A. with name and address in full and at least four cents in postage

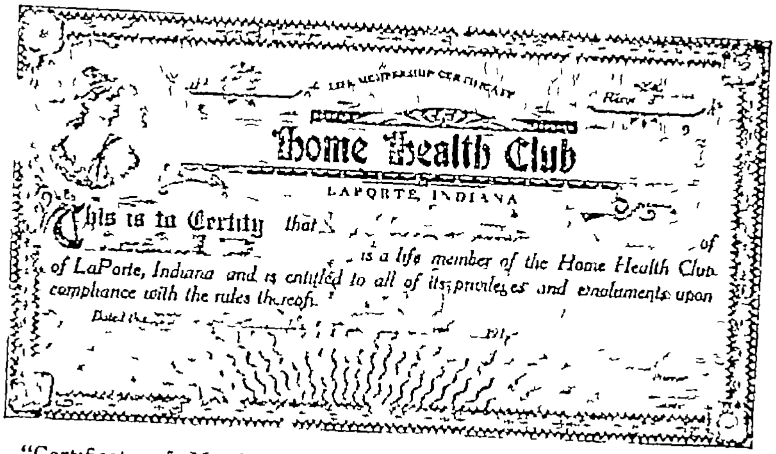
To obtain a sucker list' for his mail order patent medicine business Reeder offers to furnish newspapers with copy for a health department on the understanding that all inquiries are turned over to him Here is a sample of the copy

---

[1] Reeder's connection with the so-called Children's National Tuberculosis Society has been referred to in these pages. A reprint of the matter will be sent on receipt of a two cent stamp

"PATENT MEDICINES" BY THE SCORE

The letter from the Home Remedies Company contained "patent medicine" advertisements galore The first one described, for Abscesses, costs $2 No 4 for "Ataxia Locomotor" costs but 50 cents The eleventh on the list is for Cancer and is priced at $2 The one for Cataract comes at $1, while "Cold Feet" may be cured for 50 cents No 42 for Insanity is another half-dollar preparation while No 52 for Prostatitis costs $3 Then there is "Nocturnia" for "unnatural losses, drains and weaknesses," which "Restores Virility, Strength and Efficiency," price, postage prepaid, only $2 a bottle! And "Grandmother's Pile Cerate" at 50 cents a tube must be considered cheap, as a "relief and cure" of any form of hemorrhoids "Re-New-U" as the company's *piece de résistance,* is, of course, played up to the limit, it will give you "Health, Vigor and Vim" In order that you may *look* as young as "Re-New-U" will make you *feel,* it is recommended that you use "Cutola," "which enables you to defy old age" For Cutola



Life Membership Certificate

Home Health Club

LAPORTE, INDIANA

This is to Certify that ______ of ______ is a life member of the Home Health Club of LaPorte, Indiana and is entitled to all of its privileges and emoluments upon compliance with the rules thereof.

Dated the ______ 191_

"Certificate of Membership' in the Home Health Club, which goes with every purchase of Vol I of the club books—price $1 00

> " would restore freshness and youthful appearance to the face of an old Arizona Indian "

Those who, like Ponce de Leon, are seeking something in this line should send in a "Combination Order 6 Boxes of Re-New-U and 3 Bottles of Cutola, $5"

MAIL-ORDER CURE FOR PILES

Another case A man writes in to Reeder asking him what can be done for a long standing case of hemorrhoids No details are given regarding the case but Reeder comes back with all the glib assurance of ignorance

> "I believe that your case of piles can be entirely cured without having to resort to an operation "

As to the cause of the condition Reeder opines that "the bowels have very much to do with it," which sounds reasonable For treatment

> "You will find in Home Health Club book, Vol 3 much upon
> subject that would enable you, if observed, to successfully treat
> self at home The price of the Vol 3 is $2 00"

Further, Reeder suggests that the gentleman s
from piles "secure and use internally a preparation
toods"

> "The Home Remedies Co , Cottage Grove Ave , Opp 50th
> city handle them under the name of Modern Home Rem
> will ask them to send you some circulars describing them

CURING CANCER WITH "TISSUE SALTS"

But there is a darker side to the Reeder brand of quackery One young woman wrote to Reeder describing a case of carcinoma of the breast Reeder replied

> "From what you mention of your mother's condition I am inclined to think that the trouble may be one of Cancer of the Breast, and although such cases are considered quite severe by many physicians, they are not at all incurable There are many who have been fully restored to health without surgery, just by following the Home Health Club method of treatment, as described in the Volume 2 under the heading, 'Breast Cancer' I will suggest that you procure this book for your mother, and see to that she carries out the different suggestions given therein By so doing I predict good results. The price of the Volume 2 is $3 00 "

For this case Reeder recommended the "tissue remedies" for cancer sold by the Home Remedies Company, price $2, and declared that "Grandmother's Tumor Remedy," also sold by the Home Remedies Company, price $2, was "of great value for external use in cases of this kind" A nice business forsooth

Any man who declares that many women with cancer of the breast have been fully restored to health without surgery falsifies If he does this knowingly, and for the purpose of selling some wretched nostrums, he is a scoundrel, if he falsifies unknowingly, from the depths of abysmal ignorance, he is a dangerous quack

CATCHING THE WOMEN

Much more could be written of the Home Health Club and the Home Remedies Company and other activities of David H Reeder, did space permit It would be interesting, for instance, to describe the devious methods by which the Home

estern Reserve University,
d at his home in Frankfort
, from pneumonia

arles C Pierson, M D University of Louisville, Ky , 1907, aged 37, of Kiefer, Okla , died at the home of his mother near New London, Ia , November 15

J M C King (license, Twenty-Seventh Judicial District Board, Texas, 1880), aged 63, died at his home in Merkel, Tex., August 26, from diabetes

Edwin Forrest Philips, M D Jefferson Medical College, 1871, aged 66, died at his home in Tower City, Pa , November 17, from pneumonia

Herman C Block, M D Chicago Homeopathic Medical College, 1885, aged 63, died at his home in Milwaukee, Wis , November 10

Henry Clay Stone, M D Louisville, Ky, Medical College, 1892, aged 70, died at his home in Constantine, Ky, November 11

Levi Ormsby Johnson, M D University of Michigan Ann Arbor, 1868, aged 74, died at his home in Chicago, November 15

John Henry DeWitt, M D Jefferson Medical College, 1880, aged 60, died at his home in Philadelphia, November 14

John W Fawdrey, M D New York Homeopathic Medical College, 1892, died at his home in Corfu, N Y , November 10

Robert F Taylor, M D Pulte Medical College, Cincinnati, 1877, aged 66, died at his home in Napa, Calif, November 8

After stating that Reeder started in with an original investment of $400 and that the business had been developed until it was worth $126,000, doing a cash business of over $50,000 annually with net profits of 16 per cent., the prospectus declared that the company needed an additional $100,000 "to further advertise and push the sale of our Remedies, Foods, etc" There is the inevitable reference to fortunes made in the "patent medicine" business, and the cases of 'Bromo Seltzer" and 'Warner's Safe Cure" are cited, presumably for the purpose of exciting the cupidity of the prospective investor

THE HOME HEALTH CLUB VOLUMES

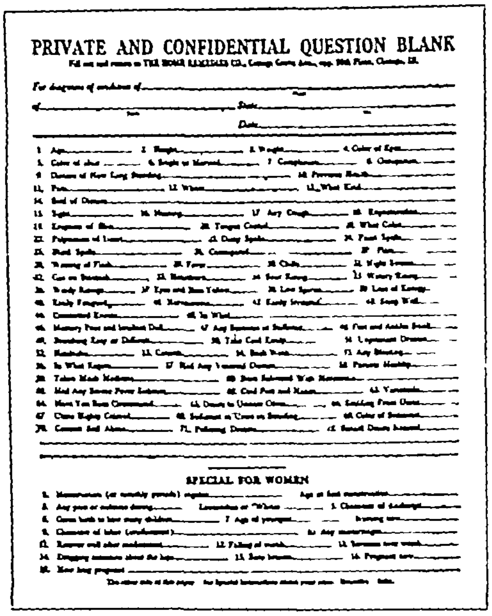
It would be possible to show by quotations from some of the Home Health Club volumes Reeder's ignorance of even the fundamental truths of medical science One quotation must suffice Reeder solemnly assures the public, through one of his books sold as recently as October, 1915, that

> Thirty six cases of diphtheria developed in one school in Chicago by the leakage of sewer gas into a hot air pipe.

In common with his kind Reeder does not omit an opportunity to blackguard the professions of medicine and pharmacy In describing himself and his methods—as a physician, not as a patent medicine' dispenser—he says

> the druggists do not love me the undertaker does not know me, and I miss his influence and my rebate my patients have a quiet time my bills unfortunately are small can t get rich very fas I don t have the advantage of swelling my bill for probate for my patients are never too sick to keep tally on the number of visits

The matter sent out by the Home Health Club, whether it be the so-called Home Health Club volumes, letters of 'advice' *Home Health* the alleged official organ of the Home Health Club or what not, has for its final object the exploitation of the nostrums sold by Reeder under the name of Home Remedies Company The entire business is one of deception misrepresentation and fraud The newspapers are deceived into accepting the Home Health Club copy, the public is deceived by leading it to believe, inferentially, that there is no connection between the 'patent medicine' concern —the Home Remedies Company—and the Home Health Club itself Reeder s writings stand as monuments to his ignorance and his methods indicate a disregard for elementary truthfulness and common honesty



PRIVATE AND CONFIDENTIAL QUESTION BLANK

SPECIAL FOR WOMEN

Every mail-order medical fraud has its diagnosis blank Here is a miniature reproduction of the one used by the Home Remedies Company

The Development of Scientific Medicine—An investigation of medical history shows two developmental periods which interlace with each other to some extent In the early days our ideas of disease and its treatment were quite indefinite and general and were founded in the main on hypotheses and theories which had no particular scientific basis In later years research and experimentation have furnished the scientific basis for the establishment of various facts and for certain seemingly sound theories in addition It is true some of the theories brought forth have been illogical deductions from the facts at hand, others have been formulated as a result of false evidence, improper technic, etc. It is fair to say however that medical theories propounded as the result of scientific research are much safer than those originating in the inner recesses of a dreaming mind It can be said, therefore that the earlier periods of generalization in medicine have passed and we are now working in the age when legitimate progress can only be made as a result of careful research and experimentation—E F McCampbell *Ohio Public Health Journal*

Correspondence

Statistics of Automobile Accidents

To the Editor—Would it not be possible for The Journal to get the facts in regard to automobile casualties in the United States? In view of the fact that your practical system of collecting and tabulating the accident results of the Fourth of July annual observation has aided forcibly in bringing about a change from a dangerous and destructive demonstration to one of sane and safe observance, might it not be possible to the same extent to make the use of the automobile safe and put a stop to the frequent deaths and injuries?

I am convinced that if the daily, or especially the annual loss of life could be ascertained and shown up in as conspicuous a manner as has been done in the Fourth of July casualties, the American people would be appalled

The American public through its legislative bodies, the Interstate Commerce Commission and otherwise, has demanded that the railroads and other public service carriers adopt and use every device and plan for safety, and yet the private citizen, with no consideration of his own or other persons' safety, uses the automobile with its many horse-power engine in a most indifferent and reckless manner

Many of these machines or cars are too often run by individuals of indifferent judgment or physical condition or by youths or others incompetent to insure the safety of their own lives or that of others traveling perhaps by safer methods

If in every case the cause or influence leading to the accident, even in a large percentage of the occurrences, whether causing death or other injury, could be ascertained and shown in a lucid form undoubtedly it would lead to better and safer conditions in handling these engine-driven vehicles Laws and regulations could be urged and enforced, making this mode of travel practically one of safety

If you can do this work you will confer on the traveling public a blessing and aid that will be inestimable

John J Coffman, M.D, Scotland, Pa

Etiology of Pellagra

To the Editor—Your recent editorial on the report of the U S Public Health Service concerning pellagra (The Journal Nov 20, 1915, p 1818) has been read with a great deal of interest, as it recalls to mind an article by Rosenbloom ("The Acetone Bodies in Diabetes Mellitus" The Journal, Nov 13, 1915, p 1715) which seems to have an important bearing on the subject

Rosenbloom states that "in health the catabolism of large quantities of protein can dissipate acidosis on account of its partial conversion into sugar' I take it he means health as distinguished from the diabetic condition

In the editorial on 'Acidosis and the Reaction of the Blood' (Sept 25 1915, p 1114) you state that metabolism in the animal body causes a regular formation of acid bodies which combine with the bases of protoplasm and blood, thus steadily operating to lower the alkaline reaction of the body

This question now presents itself Does not the protein diet which cures pellagra act by dissipating an acidosis (the particular acid bodies not differentiated yet), and may not this acidosis accumulate by *lack* of protein food?

What is acidosis? Is it not loss of reserve alkalinity sufficient to prevent neutralization of the acid bodies, as stated in your September editorial? And if it be admitted, therefore, that deficient alkalinity causes acidosis, and acidosis is dissipated by protein diet, and pellagra is also dissipated by protein diet, may we not with reason propose that pellagra is a condition of deficient alkalinity or lowered alkaline equilibrium between bases and acids?

George D Fairbanks, M D, Brownsville, Texas

Studies of Pellagra a Correction

To the Editor —I have just read the editorial on "Studies of Pellagra" (The Journal, Nov 20, 1915, p 1818) In the second paragraph of the first column I find the following As a result of epidemiologic studies, Goldberger had concluded in effect that pellagra is not a communicable disease, that it is dependent on some as yet undetermined fault in a diet in which the animal or leguminous vegetable component is disproportionately large," etc. This last word "large" is evidently a slip through inadvertence It should be "small," so that the last part of the foregoing quotation should read, "that it is dependent on some as yet undetermined fault in a diet in which the animal or leguminous vegetable component is disproportionately small," etc

Joseph Goldberger, M D, Washington, D C
Surgeon in Charge of Pellagra Investigations

Queries and Minor Notes

UTILIZABLE ALCOHOL

To the Editor —The amount of alcohol which can be oxidized by the adult human body in twenty four hours, that is, serve as a food, has been determined by a physiologist and formulated into a law Can you inform me concerning the name of the physiologist, and the amount of alcohol that can be utilized?

C C Mechling M D, Pittsburgh

Answer.—The maximal dose of alcohol has been estimated at 15 grams per day Such an amount can be taken without causing the alcohol tension in the blood to become so high that more than the usual amount will be excreted in the kidneys and lungs It has long been known that 90 per cent of the alcohol ingested is burned in the body Atwater and Benedict within the last few years have determined that as much as 99 per cent of the alcohol ingested undergoes combustion in the organism when the amount of alcohol ingested per day is equal in quantity to that contained in 6 ounces of whisky It is well known that alcohol tolerance depends largely on habituation of the individual to this substance In other words, a greater combustion of alcohol occurs in the tissues of a steady drinker than in a habitual abstainer

We are unable to find any reference to the formation of a law for the determination of alcohol utilized in the human body

---

TESTS FOR ACETONE IN URINE

To the Editor —Sajous quotes from The Journal regarding tests for acetone in the urine, those of Stock and Deniges I have no description of these tests and would appreciate the information from you

H A. W Brown, Cookstown, Ont

Answer —These tests were described in an article by Dr A E Taylor, "Tests for Acetone in the Urine" (The Journal, March 17, 1906, p 790) The technic is as follows

1 The Stock test The distillate of the urine is used From 50 to 100 c c of urine are made acid by the addition of either acetic, hydrochloric or sulphuric acid The first 10 c c. of distillate will contain all the possible acetone About an inch of the distillate is placed in a test tube, a drop or two of a 10 per cent solution of hydroxylamin hydrochlorid are added, and sufficient sodium hydroxid or carbonate to render the solution alkaline to liberate hydroxylamin, the mixture is shaken and a couple of drops of pyridin are added and the mixture shaken, then an inch of ether is added and the mixture shaken Bromin water is then added drop by drop, with mixing until the ether layer becomes yellow, then a few drops of strong hydrogen peroxid are added, if acetone is present, the ether will turn a distinctive green blue

2 The Deniges test In the test of Deniges about an inch of the distillate in a test tube is mixed with an equal amount of a solution of the subsulphate of mercury (mercuric oxid 50, sulphuric acid 200, water up to 1,000) and the mixture allowed to simmer in a stoppered flask for about five minutes A white crystalline precipitate occurs on cooling, which is very distinctive in appearance If acetone is present in excess, the test is less distinct If but a trace is present, a trace of sodium chlorid will aid the precipitation The precipitate is not soluble in dilute hydrochloric acid

---

CHOLOGESTIN AND TABLOGESTIN

To the Editor —Are the enclosed claims of chologestin and tablogestin true? Or shall I try it myself?

Jan Cepelka M D, Chicago

Answer —The "enclosed claims" are the literature issued by F H Strong Company, New York, concerning chologestin and tablogestin Chologestin is said to be a liquid of which 100 c c contains the amorphous sodium salt of glycocholic acid, 0 858 gm, true sodium salicylate from the natural oil of wintergreen, 1 07 gm, pancreatin, 2 15 gm, and sodium bicarbonate 2 15 gm, in a menstruum containing 15 per cent alcohol Each half ounce is said to contain the amorphous sodium salt of glycocholic acid, 2 grains, true sodium salicylate from the natural oil of wintergreen, 2½ grains, pancreatin, 5 grains, and sodium bicarbonate, 5 grains According to the manufacturers, tablogestin is chologestin in tablet form, and three tablets of tablogestin are said to contain the active medicinal ingredients of 1 tablespoonful of chologestin The statement is made

> "Tablogestin (and Chologestin), because of the combined digestive properties of the bile salt and pancreatin, materially aids in the intestinal digestion of the various foods and thus assists in the control of the fermentative and putrefactive changes that might otherwise ensue."

Bile salts do facilitate the action of the pancreatic juice in the intestines, but this applies only to bile salts of endogenous origin, that is, bile that is secreted in correlation with pancreatic secretion It is doubtful if the pancreatin used in this mixture could ever enter into a digestion process in the intestine As a consequence of the cholagogue action it might be admitted that it has an indirect influence on digestion in the intestine, this would, however, be offset by its disturbing influence on the digestive process in the stomach, as it is known that bile salts precipitate pepsin

State University of Iowa College of Medicine	(1898)	Minnesota
College of Phys. and Surgs. Kansas City Kan	(1898)	Missouri
University of Louisville	(1872)	Missouri
University of Michigan Medical School	(1891)	Minnesota

The following questions were asked

PHYSIOLOGY

1 (*a*) Discuss hemolysis. (*b*) Discuss the origin and fate of the leukocytes 2 What is the relation of the nerves to the movements of the intestines? 3 Discuss the influence of the nervous system on respiration. 4 Define the following terms inhibition, diffusion osmosis diapedesis perimetry 5 Discuss the metabolism of the embryo 6 Discuss color blindness. 7 Discuss inhibition in reflex action 8 Discuss the relation of the rods and cones to vision. 9 Discuss the variations in the volume of the brain due to respiration. 10 Discuss the sensation of hunger and thirst. 11 (*a*) What are the sources of uric acid? (*b*) Where and how is uric acid formed? 12 What effects are observed after section of a cutaneous nerve?

OBSTETRICS AND GYNECOLOGY

1 What is a blue baby? Give pathology and treatment of the condition 2 Ophthalmia neonatorum Give etiology pathology and treatment 3 (*a*) What are the indications for the use of forceps? (*b*) for cesarean section? 4 Diagnose tubal pregnancy before rupture. 5 Describe the mechanism of labor with a left mento *anterior position* 6 Differentiate polyhydramnios from twin pregnancy 7 Name the ligaments of the uterus and *give the origin* and insertion of each 8 Define and give etiology and pathology of cystocele, rectocele, hematocele and procidentia. 9 Describe an operation for complete laceration of the perineum 10 Give diagnosis and treatment of pelvic abscess. 11 Give cause symptoms and treatment of subinvolution of the uterus. 12 Erosion of the cervix Give cause and treatment

GENERAL MEDICINE

1 Typhoid fever (*a*) etiology (*b*) symptomatology, (*c*) pathology (*d*) diagnosis. 2 In a case of general anasarca how would you proceed to determine the underlying cause. 3 What are the early signs of tuberculosis both subjective and objective? (*b*) Describe two important tests for tuberculosis and give relative value. 4 (*a*) Differentiate acute cerebrospinal meningitis and acute anterior poliomyelitis (*b*) Give treatment of the latter 5 (*a*) Describe and give management of a case of persistent gastro enteritis in an infant on artificial diet. 6. Give ten causes of headache and indicate location of pain in each variety 7 Give a brief discussion of epilepsy and give general advice to such patient. 8 What is the significance of a blood pressure of 240 in a woman 60 years of age? 9 Give symptoms and treatment of chlorosis 10 Discuss the various types of asthma from etiologic standpoint, and give general management of one type. 11 Discuss the complications and sequelae of scarlet fever 12 What is the usual type of pneumonia in the child in the adult in the aged? (*b*) Give description and treatment of one type of pneumonia.

ANATOMY AND HISTOLOGY

1 Give formation and branches of the lumbar and sacral plexuses. (May use diagram) 2 (*a*) Classify articulations give a typical example of each class (*b*) Discuss the hip joint naming all muscles passing across the joint 3 Discuss the distribution and central connections of the auditory (eighth cranial) nerve. 4 Discuss the bony thorax 5 Discuss the pleura, giving attachments and reflections, also external *markings of its boundaries.* 6 *Give the action of* (*a*) *the sternocleido* mastoid singly and together (*b*) the psoas magnus (*c*) serratus anterior (*d*) deltoid (*e*) trapezius (*f*) iliocostalis (*g*) latissimus dorsi 7 Describe by diagram the longitudinal section of the femur showing outline and histologic structure showing normal development and regeneration 8 Give the essential differences of the appearance and structure—gross and microscopic—of the mucous membrane of the duodenum jejunum and ileum 9 Give the histology *of a medium* size artery 10 Give formation of the tributaries of the portal vein give most inferior tributary 11 Discuss the cervical sympathetic ganglia give location tributaries and branches. 12 Give histology of the mammary gland *make drawing showing typical histologic section*

HYGIENE AND SANITATION

1 Indicate the limitations of private practice as compared with public health practice 2 (*a*) What are the most important foreign ingredients in water? (*b*) Mention five methods of purifying water 3 (*a*) What prevalent acquired defect in schoolchildren's eyes is directly due to school life? (*b*) Discuss the prophylaxis of eye defects 4 Why should the registration of vital statistics be compulsory? 5 In what ways are health and efficiency of schoolchildren prompted by frequent physical examinations? 6 Describe the modern method of dealing with an epidemic of diphtheria among schoolchildren 7 What diseases are transmitted by *animals* and insects? 8 Discuss antityphoid inoculation 9 Name ten preventable diseases and indicate the mode of prevention 10 Discuss modes of dissemination of diseases which can be transmitted by indirect contact. 11 Discuss the efficiency of formaldehyd as a disinfectant Describe most efficient method of using it 12 Describe an efficient method of disinfecting excreta

SURGERY

1 (*a*) What conditions will *cause bleeding from the* stomach? (*b*) State briefly etiology symptomatology clinical and laboratory findings and prognosis of gastric ulcer 2 What symptoms and signs would result from fracture of the skull over the right rolandic area? 3 State briefly the general considerations in the treatment of gunshot wounds. 4 (*a*) Name the different varieties of goiter (*b*) When is removal of the thyroid gland indicated? (*c*) When is the ligation operation indicated? (*d*) When is no surgical interference indicated? 5 (*a*) Diagnose posterior dislocation of hip (*b*) Describe briefly the necessary manipulations to reduce said dislocation What is the after treatment? 6 Describe the operation and name structures encountered in ligation of the superficial femoral artery at the apex of Scarpa's triangle. 7 (*a*) Describe the operation *of removal of* the appendix (*b*) What are the indications for said operation? 8 (*a*) Describe the symptoms and signs of oblique fracture of head of humerus. (*b*) Describe briefly the treatment 9 Describe briefly a typical case of acute empyema giving all aids to diagnosis of said condition. 10 Give the diagnosis course and prognosis of cancer of the rectum 11 Describe the treatment of acute gonorrhea in the male 12 Differentiate gallstones from right sided kidney stones.

CHEMISTRY AND TOXICOLOGY

1 Name and give the formulas for five salts of *mercury* 2 What is the *formula* of hydrogen peroxid? What is its action on silver oxid on finely divided platinum? 3 What is bleaching powder its formula? How does it act as a disinfectant? 4 Define and discuss diffusion and osmosis. 5 Describe and discuss briefly HNO_3 its

chemical and physical properties 6 Discuss arsenic (its occurrence, properties and toxic effects, and describe the use of one antidote) 7 Discuss lead poisoning and two effective means of overcoming the same 8 Define "physiologic antidote" and "chemical antidote" and give an example of each 9 Discuss hydrargyrism 10 Discuss the indications and contraindications for the use of stomach pump 11 Discuss carbolic acid poisoning and an efficient method of treatment 12 Discuss the toxic effects of yellow phosphorus

BACTERIOLOGY AND PATHOLOGY

1 What changes are found in a stained blood smear in primary pernicious anemia? 2 What elements might you find microscopically in the sediment of a normal urine? 3 Describe the microscopic field seen in (*a*) a negative Widal reaction, (*b*) a positive Widal reaction 4 What do you look for in a microscopic examination of stomach contents? 5 Define eosinophilia, name several conditions 6 What are casts? Describe at least three varieties, and tell under what diseased conditions they are found 7 Discuss briefly the etiology of chronic interstitial hepatitis, or cirrhosis of the liver, and describe the microscopic appearance of at least two varieties 8 Describe embolism, infarction and thrombosis, and briefly discuss the pathology of each 9 Define (*a*) carcinoma, (*b*) sarcoma. Give the relative frequency of occurrence in the (*a*) breast, (*b*) liver (*c*) bone 10 Describe the gross appearance of a bone at the site of osteomyelitis 11 What are the causes of jaundice and how do *they* operate to produce this condition? 12 Define (*a*) cloudy swelling, (*b*) atrophy, (*c*) malignancy

MATERIA MEDICA AND THERAPEUTICS, PHARMACOLOGY, INCLUDING PRESCRIPTION WRITING

1 Name four commonly used mercury compounds (U S P) and discuss briefly their therapeutic uses 2 Discuss fully the possible therapeutic effects that would be expected of the following prescription ℞ Tinct nucis vomicae, 5 0, fluidextracti cascarae, 10 0, tinct cardamon comp, 25 0, tinct gentian comp, q s ad 100 0 M Sig Take one teaspoonful in half glass of water t i d, before meals 3 What is apomorphin? State dosage, indications, modes of administration and action 4 Discuss the indications and contraindications for the use of the following ℞ Kalii iodidi, 18 0, aquae dest., 60 0, syrup sarsaparilla comp, q s ad 125 0 M Sig Take one teaspoonful, well diluted t i d, p c 5 Describe and discuss three different modes of administering drugs for therapeutic purposes 6 Discuss the conditions that modify the effects of drugs 7 (*a*) Discuss the dosage of drugs as influenced by age, sex, size and weight of the individual (*b*) Define idiosyncrasy and discuss one example 8 (*a*) Discuss oleum ricini its dosage, therapeutic action and indications (*b*) Discuss three contraindications for the use of intestinal evacuants 9 Discuss the systemic action of alcohol (internally administered) 10 What is epinephrin? How is it administered? What are its principal effects? 11 Discuss salvarsan (its principal properties, dosage, best mode of administration, indications and contraindications) 12 Describe the bromid salt most commonly used (as to its physical properties, dosage, therapeutic action and untoward effects)

Indiana July Report

Dr W T Gott, secretary of the Indiana State Board of Medical Registration and Examination, reports the written examination held at Indianapolis, July 13-15, 1915 The total number of subjects examined in was 16, total number of questions asked, 100, percentage required to pass, 75 The total number of candidates examined was 43, of whom 10 passed, including 2 osteopaths, and 3 failed Twenty-seven candidates were licensed through reciprocity The following colleges were represented

Book Notices

Diseases of Nutrition and Infant Feeding By John Lovett Morse A M, M D, Professor of Pediatrics, Harvard Medical School, and Fritz B Talbot, A B, M D Instructor in Pediatrics, Harvard Medical School Cloth Price, $2 50 Pp 346 New York The Macmillan Company, 1915

The first part of this book contains chapters on the physiology of digestion, and the metabolism of the various food elements—the fundamentals, the proper foundation and introduction to the main part of the work, which is a clinical and practical discussion of infant feeding

The laboratory worker will find in the early chapters a resume of the latest views on the metabolism of early life with full reference to the work which has been done in this direction That work has been carefully sifted, and critically analyzed It is refreshing to come across such a sentence as this "It seems wise to summarize what we *think* we know about the digestion and absorption of fat" This candor and frank acknowledgment of our limitations is characteristic of the book repeatedly one reads, "but this is not proved," following the statement or description of a well-established clinical observation

Pediatricians and general practitioners will find in the work much of practical value, much knowledge and detailed information which they can apply in their everyday practice Breast feeding and artificial feeding are carefully discussed and many valuable hints given as to the management of difficult cases, the ideas set forth being in the main rational and common sense, yet "scientific" in that they are based on, and are the logical outgrowth of, facts in metabolism stated in the earlier chapters of the book This correlation or "team play" between the different parts of the work, again, is one of its characteristics

The subject of breast feeding receives the attention which its importance demands, fifty-five of the 336 pages being devoted to it Directions as to the management both of the baby and the mother's diet and daily hygiene are given in detail The more complicated subject of artificial feeding is next taken up and, cow's milk being the basis of all substitute foods, discussion of its qualities and characteristics forms the introduction to this general subject A helpful and practical part in this discussion is a description of certified milk with detailed directions as to the management of a dairy aiming to produce certified or clean milk

The opening paragraph of the chapter on general principles of artificial feeding strikes the keynote of the authors' views on the feeding of babies

> "In approaching the subject of artificial feeding it must be remembered that there are only a few food elements A baby's food may contain all of these elements, it must contain some of them it cannot contain any other elements These food elements are carbohydrates, protein and salts The carbohydrates comprise the sugars and starches"

The authors are careful to point out that expression of amounts in percentages is a method of calculation and not a method of feeding, and insist on the necessity of accuracy in our knowledge of what we are feeding our babies The misconceptions and erroneous ideas concerning this method of calculation are cleared away, and its ease and simplicity are clearly evident on study of this particular part of the book The absence of complicated algebraic formulas is refreshing The method of calculating the caloric value of the baby's twenty-four-hour amount of food is also given its just weight and importance It would have been simpler, however, had the authors used the metric system throughout in these calculations They do use it in estimating the caloric needs of premature infants, why not of older babies also?

The chapters on the problems of infant feeding will be found invaluable to those conscientious physicians who wish to practice careful and efficient methods of feeding, to know what they are doing and thereby to save life

As is to be expected in such a book of today, in the treatment of the digestive disturbances of infancy, stress is laid almost exclusively on the diet, medicine playing but little part in their proper management

While this work is by no means perfect, it is one of the best and most complete expositions of the difficult subject of infant feeding which have yet been contributed to medical literature in any language It is no exaggeration to say that if the principles as expressed in this book would be taken to heart by the great body of general practitioners to whose hands after all is entrusted the feeding of the vast majority of the nation's babies, and applied diligently, intelligently and conscientiously by them to the management of the most helpless of their patients, the shamefully high infant mortality which characterizes our own as well as other countries would be materially diminished That after all, is the object of all such work in our profession, the saving of life.

The Practitioner s Visiting List 1916 Leather Price $1 25 net Philadelphia Lea & Febiger 1915

The Medical Record Visiting List or Physician s Diary for 1916 Leather Price $1 50 New York William Wood & Co 1915

The Physician s Visiting List (Lindsay and Blakiston s) for 1916 Sixty Fifth Year of Publication. Leather *Price $1 25 Philadelphia* P Blakiston s Son & Co 1915

Among the various books peculiar to the holiday season are the annual visiting and record lists These have been offered to physicians over a sufficiently long period for their make-up to have assumed a standard form They vary however in the arrangement of the pages and in the subsidiary contents

In the "Practitioner's Visiting List" are information on the periods of dentition directions for estimating the day of confinement tables and comparative scales of weights and measures an article on the examination of the urine a list of incompatibles an article on artificial respiration tables of eruptive fevers of poisons and antidotes, of dosages and of therapeutic reminders, and an article on the ligations of arteries The book, which is for thirty patients per week, contains 192 pages which are numbered and a table of contents It is attractively bound in red leather Separate departments are devoted to general memoranda obstetric engagements, vaccinations death registry addresses of patients and nurses and a cash account. The book has a pocket for notes, and a place *for the insertion of a pencil*

In the 'Medical Record Visiting List" are a table of approximate equivalents an obstetric calendar, tables of weights and measures of dosage, and of drops and solutions for subcutaneous injections a few short miscellaneous facts a table of poisons and antidotes, miscellaneous emergency treatments articles on artificial respiration and signs of death and hints on the writing of wills The book, which is marked for sixty patients has approximately 150 pages with separate departments devoted to the daily record special memoranda consultations obstetric practice, vaccinations, deaths addresses of nurses and patients and cash account The book is attractively bound in black leather, and contains a pocket for notes and a pencil

In the 'Physician's Visiting List" are a table for calculating the day of confinement a table of contents, a table of incompatibilities poisons and their antidotes, an article on the metric system a table for converting apothecaries' weights and measures into metric a table of doses and of quarantine periods in infectious diseases an article on asphyxia, and a comparison of thermometric scales The record pages are not numbered The book, which is marked for twenty-five patients, contains approximately 100 pages, and is attractively bound in smooth black leather, with a well-fitting leather flap It has a pocket for notes and a pencil.

From this resume of contents, the relative advantages of the various lists may be estimated.

Miscellany

Pulmonary Diseases Among Miners

There has been apparently an unusual prevalence of pulmonary tuberculosis and a high death rate from it among the metal miners in southwestern Missouri This condition has attracted considerable attention and has caused some alarm in that part of the country To determine the facts in relation to this condition, the U S Bureau of Mines instituted an investigation of pulmonary diseases among miners in the Joplin district and its relation to rock dust in the mines

In Technical Paper 105, A J Lanza and Edwin Higgins make a preliminary report of their investigations The general opinion in this region was that lung diseases became more prevalent after the beginning of active mining in what is known as the sheet ground mines, and that the flint dust from drilling and other mine operations was directly responsible

The records of the State Board of Health of Missouri for 1912 show 180 deaths from pulmonary tuberculosis in Jasper County where these metal mines are located From the Jasper County Antituberculosis Society records, however, it was learned that during the same year there were 720 deaths among miners who had worked two or more years underground Not more than twelve of these deaths were from pneumonia, which was in some cases a terminal infection of tuberculous subjects Not all of these deaths occurred in Jasper County however but some occurred in adjoining counties in Missouri and others in Kansas This accounts for a considerable difference between the figures of the state board of health and those of the antituberculosis society

Some interesting comparative figures are brought out with reference to the death rate in the metal mining counties and in other counties and cities in Missouri The death rate in 1911 from pulmonary tuberculosis in Jasper County, where the zinc mines are located was 14 08 per cent of the total deaths in 1912 15 1 per cent , in 1913 15 5 per cent. In St. Francois County which is the lead mining district the percentage for 1911 was 11 8 1912 11 6, 1913 13 1 In Greene County which includes Springfield in Jackson County which includes Kansas City and in St Louis not mining districts, the percentages for 1911 were, respectively 9.27 9 33 and 8 75 In 1912 in the same counties and cities the percentages were 9 46 9 07 and 8 93 and for 1913 the figures were 7 4 8 8 and 9 1 It will be seen that in the two metal mining counties the deaths from tuberculosis exceeded those in the other counties and cities by considerable percentages

These figures have been taken into consideration by industrial insurance companies doing business in the metal mining counties One company required that all applicants for industrial insurance over 10 years of age must be examined as for ordinary insurance This rule is in operation in only one or two other districts and is said to be occasioned by the number of death claims on account of pulmonary tuberculosis Another industrial insurance company doing a large business among miners and their families estimates that at least 90 per cent. of rejections and 75 per cent of death claims are due to pulmonary tuberculosis

In determining the effect of mining conditions in producing this higher death rate, the investigators studied the methods of mining with reference to drilling, blasting shoveling housing ventilation, temperature mine water and rock dust besides some other collateral subjects with reference to the personal hygiene and personal habits of the miners

Although the mine operators have succeeded for the past two years in making many substantial improvements in working conditions underground, and state mine inspectors have given the subject attention, there is still room for improvement in the working conditions of the mines which the investigators believe to be the chief source of the lowered state of health which results in the large incidence of tuberculosis Rock dust is the chief vehicle of harm, done directly to the lungs by reason of the hard sharp comparatively large flin y particles of which it is composed This dust is made by the drilling and blowing out of dry holes, by "squibbing," which means the blasting in holes in which the drill becomes blocked, and by the blasting of large boulders in the chambers of the mine, as well as from shoveling and dumping the ore

The mine workings in sheet ground mines constitute practically one large open chamber which allows the dust to disseminate Although the amount of dust in the air is not, comparatively, large, practically every man underground is exposed to the dusty atmosphere during his entire shift This dust, it is believed, could be largely prevented, and two methods are mentioned the use of some type of drill that provides for water passing through the core of the drill steel into the drill hole, and the spraying of the drill holes, ore faces and broken rock by means of a hose to which a nozzle is attached A separate water line should be laid to every working face None of the mines are yet fully equipped with water drills Strict rules should be enforced against squibbing and boulder blowing while the shift is underground, and against the blowing of drill holes at all times Ventilation should be improved by the opening of new shafts whenever practicable By way of legislative provisions it is recommended that state mine inspectors should be empowered to decide what constitutes a dusty mine, and that operators should be compelled to run a water line to each working face Every miner should be compelled to use the water Breaking boulders by means of powder or dynamite should be prohibited, except when the shift has left the mine Blowing of drill holes without first wetting them should also be prohibited

It is believed, further, that a workman's compensation act would go far toward improving safety and sanitary conditions in the mines of the Joplin district

The Larger Relations of the Hospital

The final test of a hospital's efficiency, according to R M Bradley (*Modern Hospital*), is not merely the treatment which it accords to the patients which it receives but also the impression which it makes on the whole sum of sickness in the community He summarizes the results of a canvass of two districts in New York, with a view to ascertaining this point

It appeared that, in a total population of 17,000, 86 6 per cent of the cases of sickness were cared for at home and not at the hospital, and that 75 per cent of the typhoid deaths and 80 per cent of the pneumonia deaths occurred at the home Why were these desperate cases not cared for by the hospital? Another canvass to ascertain the hospital needs was made of all ascertainable cases of sickness in a central New York district with about 10,000 inhabitants The number of beds needed was figured out, but analysis of the causes of illness sadly disarranged the beautiful estimate For instance, the figures called for accommodations for many typhoid patients, but reflection suggested a few drainpipes as "a more radical and less expensive remedy for that particular ill" Certain unfortunate girls had no place where they could receive proper care during confinement, but would it not be better to place such helpless and feebleminded creatures under permanent custody than to aid them in producing offspring like themselves? The dwellings of many families were no better as places to live in than to be sick or die in "Was the remedy better housing or more hospital beds?"

Bradley suggests that in future hospital planning will be carried out in connection with a social survey that will take account of the main sources of preventable illness While, on the one hand, hospital provision must tend to increase as the people learn reliance on hospitals in proper cases, on the other hand it should tend to decrease with the application of methods of disease prevention and a system of home care that will prevent hospitals from being overloaded with the less urgent cases Bradley indicates a method of tabulation intended to bring out how far the hospital is meeting the demands of the highest social efficiency For such a purpose cases might be classified as (1) real hospital cases (cases in which the patients cannot without undue trouble and expense or danger to the community be cared for outside of the hospital), (2) cases in which home care or nursing is defective, and (3) cases in which the patient has no home He also suggests that account be taken of the days during which convalescent patients have to be retained in hospital (thus crowding out more urgent cases) because there is no suitable place for them elsewhere A system is needed which will coordinate the hospital with other social agencies

Medicolegal

Liability of Associate Surgeon for Leaving of Sponge in Wound

(Walker vs Holbrook (Minn), 153 N W R 305)

The Supreme Court of Minnesota affirms a judgment for $1,000 damages against the defendant for alleged malpractice in the leaving of a piece of gauze or sponge in the body of the plaintiff in an operation for appendicitis and other troubles The court says that one of the incisions never healed, but the presence of foreign matter, though the wound was inspected, was not demonstrated until parts of the gauze began to come from the wound It was in the plaintiff's body nearly a year The first contention of the defendant was that there was no contractual relation between him and the plaintiff, and the evidence relating to his employment was somewhat unsatisfactory It was, however, sufficient to present the issue to the jury which could properly find that the defendant was employed by the other surgeon acting on the suggestion of the plaintiff If this was true, he owed the plaintiff the duty of exercising reasonable care and skill, and the question as to whether or not he performed that duty was for the jury The defendant's second contention was that he was not in charge of the operation, but was merely an assistant of the other or operating surgeon, and merely did the things which he was told to do, and that consequently the negligence or want of care, if any, was that of the other surgeon, who had died The evidence was conflicting as to whether or not the defendant was employed by the other surgeon on his own motion or at the suggestion of the plaintiff Whether or not the defendant was merely an assistant to the other surgeon, employed by him on his own initiative, doing the things that he was told to do, so as to free him from any charge of negligence, was, under the evidence, a question for the jury There was evidence tending to show that the defendant actively participated in the operation, that he consulted with the operating surgeon, that he assisted in sewing up the wounds, and that he handled the instruments and did other things, from which, if the jury believed the testimony, they could find that he was performing the operation jointly with the other surgeon The theory on which the action was tried and submitted to the jury was that the plaintiff was injured by the failure of the defendant to exercise reasonable care and skill, a duty resting on the defendant under the circumstances The trial court properly submitted the case on this theory The defendant, whether at the invitation of the plaintiff or of the other surgeon, associated himself with the latter and took an active part in the operation In thus undertaking to act, he owed to the plaintiff the duty of performing the operation with the reasonable care and skill which ordinary surgeons use under such circumstances It was not charged that there was any lack of skill The evidence all pointed to want of care The law requires reasonable care But this care must be proportionate to the risks to be apprehended and guarded against The degree of care must be commensurate with the circumstances under which the transaction is had, the seriousness of the undertaking, and the dangers to be anticipated Reasonable care may thus under certain circumstances be the highest degree of care A third contention of the defendant was that a certain custom obtained in the hospital where this operation was performed, and that the defendant and the other surgeon conformed to that custom, and to the practice and custom of reasonably skilled and careful operating surgeons at the time that the operation was performed. Evidence that the defendant followed the usual practice of surgeons in leaving the care of the sponges to the nurses, and that such was the general practice among good surgeons up to the period when the operation was performed, and that good surgeons at the time of the trial still followed that custom, was proper under the circumstances, but not conclusive on the court or the jury. General custom is not as a matter of law due care.

Validity of Statute Prohibiting Advertising to Cure Sexual Diseases—Sufficient Indictment

(State vs. Hollinshead (Ore.) 151 Pac. R. 710)

The Supreme Court of Oregon affirms a judgment of conviction of the defendant of having violated section 2095 of Lord's Oregon Laws, as amended in 1913, by advertising a certain proprietary remedy, guaranteed to cure gonorrhea or gleet. The court says that the indictment very clearly and specifically stated that the defendant violated the law 'by then and there exposing and exhibiting to the view of a large number of persons, and displaying and publishing, in the aforesaid county and state, a certain advertisement, to wit, a sign, in words and figures as follows, to wit," and then set out in full the objectionable matter. This was clearly sufficient, although the defendant contended that the indictment did not contain a statement of the facts constituting the offense with sufficient clearness and distinctness to notify him specifically of the offense for which he was to be tried.

But the chief contention of the defendant was more serious, being the assertion that the statute on which the prosecution was based is unconstitutional and void. It was contended that the act is defective, in that the subject thereof is not fairly expressed in the title, and that the act embraces more than one subject. The title of the original statute as enacted in 1909 reads thus: "An act to prohibit the advertising of treatment or cure of venereal or other diseases, declaring the same a misdemeanor and prescribing a penalty therefor." The court thinks it will be conceded without argument that this title fully covers the scope of the act itself. The title of the amendment reads thus: "An act to amend section 2095 Lord's Oregon Laws, relating to advertising to cure sexual diseases." In the New Standard Dictionary the word 'sexual' is given as synonymous with "venereal,' and is so accepted in common usage. It follows that this contention of the defendant must fail.

The next point presented was that the act is unconstitutional and void in that it is class legislation, and is a violation of the constitutional guaranty of equal protection of the law. This may well be considered in connection with the final proposition that the act is void because it is not within the legitimate scope of the police power of the state and is a violation of the constitutional provision that no person shall be deprived of life, liberty, or property without due process of law. For many years it has been recognized by publicists and legislators that some drastic action is necessary to check certain social evils and to protect youthful and inexperienced humanity, not only from easy access to vicious and immoral practices, but also from the schemes of designing men, who, for the sake of financial profit, would prey on the calamities of the unfortunates who have sowed the wind and reaped the whirlwind. Further than this, it has been thought that the act of spreading broadcast, by means of advertising, the idea that certain venereal diseases are easily and cheaply cured, is against public policy, in that it has a decided tendency to minimize unduly the disastrous consequences of indulging in dissolute action. These views were evidently the moving principle of the legislators in the passage of the act under discussion. The purpose of the act is clearly in the interest of the public morals. It is not class legislation, for it applies to all who may be engaged in a like business.

The court regards the statute as a valid exercise of the police power of the state.

SERUMS AND VACCINES

General Principles of Vaccine and Serum Therapy

Dr. Thomas McCrae: Two factors obtain in an attack of an infectious disease—the virulence of the infecting organism and the resistance of the individual. Each may vary, and the possibilities for differences are endless. The contest between the infecting organism and the individual attacked gives the features of the disease. Recovery from the attack means immunity, in some cases permanent, in others, temporary. The toxins can harm only when they unite with the cells, free in the blood they have no power to do harm. The toxin may unite with the cell and kill it, or it may unite and do little damage. This contest between the infecting agent and the body cells is an exceedingly specific matter. On this rests much of the principle of vaccine therapy. For example take the number of strains of the pneumococcus. Infectious organisms find only a limited opportunity for development in the body, and in the majority of instances they are destroyed. The fact that many of the tissues of the body possess an immunity makes vaccine therapy possible. We speak of immunity under the two main heads of active and passive. The active is that in which the body manufactures its own protective substance, the passive, that in which the protective substance is introduced from without. In therapy we have the same division, active and passive immunization. The former is by vaccine, the latter by serum. The underlying principle in active immunization is by the use of vaccines to help the organism to produce the protective substance. The dose of vaccine must be such that the patient can overcome it by his own resistance, which is a difficult thing to estimate. In the use of vaccines it is advisable to make a strong distinction between acute and chronic infections. In the chronic form there is not the same danger as in the acute; the body has become more accustomed to the organism and dangerous reactions are not so probable. In very acute cases we should keep in mind the danger if the infection is very severe and the body resistance low. In estimating the results of vaccine therapy, it should be remembered that in the majority of cases the body itself is well able to take care of the infection.

It is dangerous to draw conclusions from the results of vaccine therapy in a limited number of cases. As a general rule we are considerably safer in giving vaccine subcutaneously than intravenously. Small doses are to be employed at first. In the production of passive immunization we are introducing help from without. This is most useful in acute infections, and as with vaccines, the serum must be specific to give the best results. It should be given as a rule in large doses. The method of administration should be considered, whether this shall be subcutaneous, intramuscular, subdural or intravenous depends on conditions. There is not the same danger of doing harm as with the vaccines. In some instances we combine the two methods. In reference to the whole subject, we may say that we are dealing with very delicate reactions; how delicate it is often impossible to know. Caution is necessary, particularly in acute infections. The reactions are extremely specific, therefore, we must have specific knowledge and specific remedies before we can interfere successfully. In talking about the principles of vaccine therapy, we must not forget that perhaps the greatest principle of therapy is to be certain that our remelies will do no harm Therefore, in regard to the use of vaccine, especially, let us always have a clear understanding of what we are doing, we agents with intelligence, and above all, be sure that we are not doing injury instead of good

Vaccine and Serum Therapy of Local and General Infections

Dr Alfred Stengel No one can properly approach a discussion of vaccine and serum therapy without giving some sort of expression to his views regarding the general principles on which such treatment is based, and the extent to which his practice would be governed by the scientifically demonstrated principles that are applicable In February, 1914, in a discussion before the Royal College of Physicians in London, Dr Rolleston said he would divide the opinions regarding vaccine therapy into three groups 1 The optimistic, held by those who, while under the fascination of a new conception of a really rational treatment, have seen successful cures This attitude is usually modified in time 2 The pessimistic, more often expressed in private than in print, according to which vaccines never do good, and owe their apparent use to coincidence or suggestion 3 The doubtful or open minded Rolleston said that he belonged to the last class I, myself, claim to belong to the first, freely confessing that the fascination of theories supported by some demonstration in experimental investigations quite carried me away I am not quite certain that I fulfil Rolleston's idea of the latter part of the characterization of Group 1 because I am not conscious of having had my views modified Like others who have made trial of these methods of treatment, I have sometimes seen brilliant results, and again, have failed to find them in cases apparently entirely similar, which may indicate that we have much to learn regarding practical details There are many reasons, however, why I feel that an attitude of conservatism should be held on the matter of vaccine and serum therapy, and I cannot but recall the contrast between the attitude of the profession toward antidiphtheritic serum and that now exhibited toward vaccines, all sorts of serum and similar preparations Whereas antidiphtheritic serum, whose claims to recognition were founded on the most rigidly scientific demonstrations, was received with scant courtesy and even denied for a considerable period of time, the professional attitude at present is to receive with open arms any and all sorts of vaccine and serum treatments resting on no sort of foundation, or on the flimsiest evidence Sometimes it has been said that progress in drug therapeutics has been largely based on experiment in man, and that serum and vaccine therapy should be advanced by the same method There is a fundamental difference, however, in these two methods of treatment So long as the gastro-intestinal tract is functionally intact, the administration of any nontoxic drug is a matter of little moment, and even toxic drugs in sublethal doses may be tolerated, or if irritating, rejected The subcutaneous or intravenous injection of vaccines or serums is, however, an entirely different matter, and we should not forget the distinction Another reason for conservatism is that vaccines and serums are distinctly capable of doing harm It is often said that in serious diseases such treatment may as well be tried because it can do no harm This statement is grossly incorrect On the contrary, I could easily produce evidence that both vaccines and serums are capable of causing injurious effects I do not wish to be misunderstood in offering these reasons for a more conservative attitude toward this whole question No one who has read the medical journals or the newspapers need be apprehensive that vaccines and serums will fail to receive a fair trial, but there is grave reason to suspect that they will be abused

Dangers and Futility of the Indiscriminate Use of Serums and Vaccines

Dr M Howard Fussell A serum is specific only against the toxin generated by the organism used in the preparation of the serum A vaccine will generate immune bodies only against the organism from which the vaccine is made Failure to grasp these facts is perhaps responsible for the greater part of the indiscriminate use of vaccines and serum Unfortunately, many practitioners base their belief in the value of vaccines and serums on the statements of manufacturing firms and their detail agents Many manufacturing firms have distributed to the medical men brochures containing statements some of which are true and others half true and misleading It is questionable whether general infections are favorably affected by vaccines Successfully to treat general or local infection with serum or vaccine we must use the serum or vaccine made from the causative organism To use any stock vaccine with propriety, one made from the type of organism to which the infection is due is essential A mixed or combined vaccine is composed of entirely unrelated organisms, not different strains of the same, and it is certainly carrying the use of shotgun prescriptions to a wide range to give organisms of entirely different characteristics Such treatment is futile and may easily be dangerous Phylacogens, according to their manufacturers, are neither serums nor vaccines, but "sterile aqueous solutions of metabolic substances or derivatives generated by bacteria grown in artificial media" "The phylacogens are made from a large number of species of the well-known pathogenic bacteria" I have read many of the case reports of patients said to have been cured by some of these specific phylacogens They are equaled by many of the testimonials of "patent medicines" seen in the daily press I consider the use of such preparations as these both dangerous and futile, dangerous because of the severe reactions which take place, futile, because their use is not founded on proper observation or followed by justifiable results The dangers in the indiscriminate use of serums and vaccines are due chiefly to a misunderstanding of the basic laws and the following of the uncensored advice of the manufacturers of vaccines and serums

Discussion on Serums and Vaccines

Dr S Solis Cohen The keynote struck in the papers may be summed up in the word "caution" We must use these remedies intelligently, for definite purposes, under definite conditions That may be said of any remedial measure At the present time we must use a scientific empiricism in the application of biologic agents, for I am not so sure that we have arrived at a scientific explanation of the action of vaccines

Dr James Tyson From my observation of vaccine and serum treatment in the hands of other men, I am convinced that the treatment is justified in a great many instances, especially after a trial of the older methods of treating such affections

Dr H M Christian In the department of medicine in which I am specially interested I think we have fairly well crystallized in our minds the futility of vaccine therapy

NATIONAL ASSOCIATION FOR THE STUDY OF PELLAGRA

Third Triennial Meeting, held at Columbia, S C, Oct 21 22, 1915

(Continued from page 2029)

The Prevention of Pellagra A Test of Diet Among Institutional Inmates

Drs Joseph Goldberger C H Waring and D G Willets Washington, D C Published in *Public Health Reports,* Oct 22, 1915, p 3117, and commented on in "Studies of Pellagra," editorial, The Journal, Nov 20, 1915, p 1818

The Treatment of Pellagra by Diet

Dr David G Willets, Washington, D C In June, 1914, the treatment of acute pellagra by a rich animal protein diet was begun at the Georgia State Sanitarium, Milledgeville, Ga, by W F Lorenz of the United States Public Health Service, under the direction of Surgeon Joseph Goldberger Beginning Aug 19, 1914, the work was continued by me until Oct 24, 1914, when the therapeutic study was discontinued, and the preventive study reported in another communication (Goldberger, Waring and Willets) was begun

Forty-three patients were treated Of this number eight are excluded because death occurred after brief periods of observation, three because of the presence of complications in themselves competent to cause a fatal outcome, and two because they were transferred from the ward with severe complications after brief periods of residence on the pellagra ward Of the remaining thirty patients eleven improved seventeen recovered and two died, giving a mortality of 6 6 per cent The treatment given was simply a generous diet, rich in animal protein, in some of Dr Lorenz' cases bismuth subnitrate, emulsion of cod liver oil and an antiseptic mouth wash were prescribed

No far-reaching conclusion can be drawn from the results obtained in this work Those who have cared for insane patients will appreciate the difficulties one encounters in dealing with this class of individuals Many of the patients were so negative or so excited that their actions could not be controlled These factors all tend to retard favorable results from any form of treatment. A mortality of 6 6 per cent in this type of patient must, therefore, be considered as an extremely encouraging result and this must be kept in mind in judging the merits of any treatment other than diet

DISCUSSION ON PREVENTION AND TREATMENT OF PELLAGRA BY DIET

Dr. J F Siler, Washington, D C In our work in Spartanburg County we have constantly noted that diet has a very great deal to do with pellagra, its cure and prevention As to whether an incomplete or poorly balanced diet is merely one of the most important predisposing factors or is the one essential factor still requires demonstration Many epidemiologic observations warrant the inference that an incomplete diet is only an important predisposing factor bearing somewhat the relationship to pellagra that it does to tuberculosis It has been a common observation with us that if a patient suffering with acute symptoms of pellagra followed our advice in applying the same treatment for pellagra as for tuberculosis—an abundance of fresh eggs and milk—his chance of recovery was much enhanced Also, patients carrying out this line of treatment would, after recovery, revert to their former incomplete dietary, and yet pass through the following one, two, three or four years without any manifestations of pellagra. Some schools hold even today that tuberculosis is essentially a food deficiency disease for which the treatment is eggs and milk. It still remains to be demonstrated scientifically whether eggs, milk and fresh meat bear the same relationship to pellagra as to tuberculosis, or, on the other hand, contain large amounts of true pellagra-preventing vitamins as do peas and beans contain large amounts of beriberi-preventing vitamins

Dr. H. F Harris, Atlanta, Ga I arrived at Dr Goldberger's conclusion shortly after I began working on the subject ten or twelve years ago Subsequently I discovered that this idea was very old Solair advanced the view definitely in 1781 He took ten patients and fed them on good food for a year and was rewarded by observing that the eruption failed to appear next year and good results were observed after that I believe there are certain possibilities of spring recurrences being explained by bad maize It is well known that the starches of maize and other cereals when acted on by molds produce poisons, and in accordance with this is the modern acceptation of pellagra by the Italian writers It has been shown that it is too cold for molds to grow naturally in winter They develop in the spring, and toxic phenols develop in the maize in large amounts When the temperature goes up, the action ceases, and the poisonous phenols are perhaps changed In summer this does not occur, while in the fall these poisons begin again to form, and it would be assumed that these poisons would be most likely to recur Pellagra has uniformly and persistently occurred where people have persisted in eating maize, and disappeared where they ceased to eat it

Dr. James Adam Hayne Columbia, S C. If you can give a man food in proper proportions in such a way that he can assimilate it, you will strengthen his resistance and make him throw off the disease. That is as far as the question of diet can affect the causation of disease If a man who knew nothing about tuberculosis was taken to a tuberculosis camp and told that the patients were given meat, eggs, milk and other food in proper proportion, that their temperature was reduced, their physical well-being improved, and that, to all intents and purposes when they left the institution they were well would he conclude that a properly balanced ration was the cure for it? He might conclude it was a cure for tuberculosis, but would he conclude that an improper diet was the cause of tuberculosis?

Dr. W J MacNeal, Washington, D C There is poor nutrition among people who have good things to eat. Other factors in the body besides the food may predispose to the disease We certainly have these summer diarrheas among well-to-do people Children's diseases occur among those who have good diet as well as among those who do not Overwork is a factor The question of childbirth and operations are predisposing factors in pellagra The nutrition of the aged gradually diminishes Poor diet is only one factor We have poor nutrition throughout the world, but pellagra is a local disease in its first attack, not necessarily in its recurrences and that is the important dstinction to which Dr Goldberger referred

Dr J W Babcock Columbia S C. I deny that pellagra is a local disease You will find pellagra in all parts of the United States and in Canada, it is a universal disease

Dr. G C Mizell Atlanta Ga The way the foods that Dr Goldberger prescribed are prepared has a bearing that he has not spoken of in his paper Four years ago I believed in forced feeding and in a great deal of food, and I pushed it I now know that I lost some cases because I forced food It is a mistake to force food on a pellagra patient, or to take a nursing infant from the breast Let the infant continue nursing results will bear out the value of this suggestion Dr Willets' patients were extremely emaciated The weight of the patient, when he comes to you, will have a lot to do with the course of the disease Emaciated patients recover more rapidly and are less likely to have a recurrence

Dr David G Willets Washington, D C I fully appreciate that there are some very severe cases in which forced feeding must be used with caution, but to make the general statement that forced feeding of pellagra is incorrect would give a wrong impression In the majority of acute cases the patients really need forced feeding At least, that is the way it impresses me, from the response of my patients to diet I wish to say that in the work I did and reported here, extremely careful attention was paid to the patients They were weighed at very frequent intervals and I took change in weight as being a pretty good index as to how the patients were getting on Dr Mizell is right about certain severe cases One should proceed with caution in feeding the patients It is best to give them small quantities at a time but frequently

Dr. Joseph Goldberger, Washington, D C. It is an interesting psychologic phenomenon that the profession is extraordinarily interested in the discussion of pellagra I can get a rise out of physicians any time the cause of pellagra is mentioned, and they will talk by the hour, but if one diplomatically suggests the very simple or practical device of treating the patient they will change the subject There is an adage to the effect that "the proof of the pudding is in the eating thereof" and the only thing that I care to say in closing is Suppose we stop talking so much We do not have to inject salvarsan etc

Some Phases of the Work of the Robert M Thompson Pellagra Commission

Dr. W J MacNeal, New York This is essentially the second progress report of the Thompson-McFadden Pellagra Commission as published in September and October, 1914 in the *Archives of Internal Medicine*

DISCUSSION

Dr. Joseph Goldberger, Washington, D C The commission states that its extensive dietary study failed to indicate the presence of either a pellagra-producing or a pellagra-preventing food in the mill village populations studied, and it expresses the opinion that no such things exist By reason of the inadequacy of the method of analysis applied to the data, no conclusions whatever are permissible That this is so is perhaps best illustrated by referring to that portion of the dietary study dealing with milk The commission suggests that the daily use of milk has preventive value, 13 5 per cent of the families using milk daily had one or more cases of pellagra, 22 5 per cent of those using milk habitually (as often as twice a week) had one or more cases, and 13 6 per cent of those using this food rarely had one or more cases Their results show that the "daily" and the "rare" use of milk have preventive value This singular paradox alone is enough to convince the impartial student that this dietary study cannot be seriously considered When the data in this study are properly viewed one finds clear indications of the existence in the mill villages studied by this commission of an inverse proportional relation between the percentage of families using meat and using milk "daily" and "habitually" and the degree of pellagra prevalent in that village In other words, of two groups of villages, that group which shows a larger proportion of families using milk "daily" and "habitually" will have the smaller amount of pellagra

The commission considers the results obtained from its domiciliary study as conclusively proving that pellagra is an infectious disease, but as in the dietary study, no conclusion whatever is permissible The fundamental method of analysis employed in this domiciliary study is defective in that, as regards the so-called second zone, the percentage of incidence of new cases varies not alone with the actual number of cases, but also with the position of the houses in which the new cases may happen to appear

As for the relation of pellagra to sewerage, as shown by the practical freedom of the sewered sections of Spartanburg, this may be an instance of "false correlation" When we recall that pellagra is essentially a disease of poverty an explanation for this seemingly mysterious phenomenon at once suggests itself In a community having a sewered section and an unsewered section, it is very likely, and in Spartanburg it actually so happens, that the sewered section includes the best residential portion of the town The sewered section is that part of the town in which the well-to-do people live, in which even the neophyte pellagrologist would not expect to find much pellagra, sewers or no sewers

Dr Roy Blosser, Atlanta, Ga Dr MacNeal ignores sensitization altogether, but I think this is one of the greatest established facts in regard to certain foods It means that during the development of pellagra the people who develop it may be using only a fractional part of the foods used by those who do not develop the disease, but they are so sensitive that the smaller amount has a greater effect He did not say what percentage of the total number who had pellagra used maize That is of vital importance His dietary study is valueless unless he takes into account all the foods eaten I am not saying this particularly because he left out sugar-cane products He did not show what they ate in the sections with the good water closets, where they had never had pellagra He did not show whether, when they installed good water closets, there was any change in what they ate That I consider of great importance He thinks the infection from bad closets might combine with the poor nutrition to cause pellagra, but he did not show that there was any poor nutrition In my experience very often during the time that they show their earliest symptoms of pellagra, they show evidences of unusual nutrition, they are fat and overweight

Dr J F Siler, Washington, D C It must be remembered that when we began our studies, corn itself was the article incriminated, and this study was made primarily to determine whether corn or any other particular article of food could be correlated with the occurrence of pellagra We thought of considering groups of foods, but it took two of us about three months to work out the correlations presented by Dr MacNeal So far as the grouped consideration (statistical) of the diet of the individual is concerned, we found it to be most feasible to consider only the pellagrins We were very much struck by the sewerage question, and the observations were so striking that we considered it desirable to present them in order that they might or might not be confirmed by other observers We investigated two mills at Union, S C, in 1914 One had the water carriage system of disposal and the other open surface privies At these two mills we found that pellagra had diminished very markedly in the sewered mill following the installation of a sewage disposal plant, while in the other no such change for the better had occurred Dr Maddux says that few new cases occurred in 1914 in the sewered mill, while a large number of cases have occurred in the unsewered mill Dr Weston told me of two mills in Columbia, one with sewers and the other without, and that he knew of only two cases in the sewered mill village, and both of the patients had the disease on arrival In the unsewered mill a large number of cases occurred in 1915 It is wise to follow such observations over a long period of time before arriving at any definite conclusions

This dietary study has been a correlation as to the frequency of the use of certain foods Of one food, in which there exists no correlation, no mention has been made Practically every family throughout the South uses wheat flour every day It forms the most important bread component of their dietary Whether any changes have occurred in the milling of wheat flour in the last ten or fifteen years which could have removed the hypothetic pellagra-preventing vitamins, I do not know I know that before the Civil War more whole wheat flour was used in the South, but so far as I have been able to learn, no important changes in milling have occurred during the past ten years It might be possible that the finely milled white wheat flour could bear somewhat the same relationship to pellagra as does highly polished rice to beriberi Last winter I saw a patient from the South who had suffered a very severe attack of pellagra in 1911, and in securing a history of her food habits was somewhat surprised to learn that for two years prior to the initial attack of pellagra she had been in the habit of eating not less than twenty-four whole wheat biscuits a day to correct constipation

Dr G C Mizell, Atlanta, Ga In a series of eighty-two cases out of the 100 that I presented here in 1912 which came under observation in 1911, or before, there were six families containing more than one case This series represented sixty-eight families, composed of 341 persons Up to date there has not been a single new case in these families since 1911 In addition to this series of cases, I have been able to follow up another series of eighty-three cases which came under my observation from 1911 to 1913 The last series shows the same points of interest as the first series The two series total 165 cases, representing 147 families, composed of 764 persons

Dr James D Bozeman, Fort Worth, Texas Until October 10 we had treated in our institution, 114 cases of pellagra this year, representing about 41 per cent of admittances The majority of these cases were drawn from Texas territory, about 80 per cent represents the families of ranchmen or farmers who own their own farms or ranches Now these farmers or ranchmen will tell you that their chief diet is milk, butter, eggs, beef and fresh hog meat, with of course the usual garden vegetables, and it is seldom that you find one who will admit that he does not live off the products of his own ranch and garden If you ask them about the consumption of corn bread, they will likely laugh at you and reply that corn is raised to feed to horses and hogs Some 15 per cent of these men will tell you that they have corn meal on their ranch and that some of their boys (cowboys) enjoy corn bread, but we hardly ever have a cowboy in our institution for treatment When asked about lard they will tell you that they do not use cottonseed products, but that the lard they use is made from their own hogs, raised and killed on their own ranches

Dr H F Ivy, Whitney, Texas I believe that pellagra is an infectious disease Those of us who have done much surgery find that often a patient, unsuspected as a pellagrin, after an operation will develop a fulminating case of pellagra I find that some persons after a long period of nursing—not of pellagrins—and anxiety, have developed pellagra An excessive diet of sugar may eventually so derange the system that it will put us below par Even too many beans will produce toxemia

Dr. W J MacNeal, Washington, D C The problem which confronted us was the analysis of the mass of data recorded on cards in the symptomatic fashion I think the one method commonly used with at least 1,000 comparable observations is that adopted by Davenport and by Pierson Where there are a number of variables in group statistics the theory of chance presupposes that in a large group under observation—anything above 1,000—any neglected factor will be of no avail That is to say, the influence of any factor neglected in the analysis will have only a chance effect which will equalize itself in such a group We were dealing with about 6 000 individuals and observations, and this was quite justified

We must do something with the data besides theorizing with them We must try and show some correlation That is what we have attempted to do by the statistical method It is probably unnecessary for me to point out that the table which Dr Goldberger cites specifically relates to pellagrins and total families in which a case existed and did not originate This is the correlation between the existence of a case in a family and the use of milk in that family at the time of our observation So from our point of view, this table has very little importance Of course it all depends on whether or not you think there is any real difference and importance in distinguishing between this All of our work has taken into consideration the first attack as quite different from the subsequent attacks and any one who has really studied pellagra and has followed it must acknowledge that there is a distinct and important difference between the first attack and subsequent attacks The first attack occurs in certain definite places, the second attacks may occur anywhere. It is only by distinguishing between first and subsequent attacks that we have been able to bring out these distinctions

(To be continued)

SOUTHERN MEDICAL ASSOCIATION

Ninth Annual Meeting held at Dallas Texas Nov 8 11 1915

(Concluded from page 2031)

The Small Town The Neglected Unit in Sanitary Administration

Dr. A. W Freeman, Washington, D C The fundamental sanitary needs of the small town are those of water supply and excreta disposal The shallow well and the privy must be condemned Neither the well nor the privy is sufficiently protected A public scavenger and the can privy should be advocated Such privies are easily cleaned, and the breeding of flies is kept down and public health protected The great need of the South today is the improvement of the rural home.

Sanitation of the Rural Home

Dr. R. N Whitfield, Florence, Miss The rural home needs more improvement, as a rule, than any other home In the South the rural population is greatly in excess of that of the cities and towns and the public health services have been performed in the cities and towns to the exclusion of the rural districts One exception has been made, and that is the work done by the Rockefeller commission which has been laboring five or six years in eleven of the Southern States A full-time health officer should be placed in charge of every county in the South, and he should be a capable and competent man.

Intensive Community Health Work

Dr. John A. Ferrell, New York Intensive community health work differs from ordinary health work in that a concrete health problem is taken and adhered to until measurable progress has been made It is limited to a relatively small circumscribed area instead of being diffused throughout a large area, such as a state or a county A detailed record or a survey is made of the area selected including every home, school, church, road and stream, and usually the information is shown on a map Every home is visited and inspected, and every person examined as far as practicable, with reference to the particular health problem under consideration A record of the disease in the past and its probable consequences is made so that when the work begins there is a definite starting point.

Rural Sanitation in the South

Dr. J Howell Way, Waynesville, S C The employment of a full-time country health officer should be on scientific merits rather than on a political basis The chief difficulty in county work is the lack of a well-defined plan of procedure A rule of standards and model system will be worked out for counties soon Eventually when methods of rural sanitation become standardized and our counties grow in population as well the unit system operated by state boards of health will naturally and appropriately give place to the whole-time county health officer, but for the next five to fifteen years the unit system possibly is destined to exercise a more practical and helpful influence on the progress of rural sanitation than can be invoked by any adherent solely for the whole-time county health officer plan, which so many counties do not feel they may institute as yet

Immediate Necessity of Intensive Health Work in the South

Dr. A. L. Lincecum Austin, Texas Housing conditions are deplorable, especially among the tenants in the farming districts The absence of screens on the doors, windows and porches of these homes costs annually for treatment of malaria more than the expense of screening would be

Use of Radium in Uterine Bleeding Due to Myometrial Dgeneration

Dr. C. Jeff Miller, New Orleans Radium has proved a boon in inoperable cases of carcinoma, but I would not recommend it as the sole treatment in operable cases The only treatment that promises relief from cancer is its early removal by surgery I have used radium in a number of cases with beneficial and satisfactory results Radium, when properly screened may be used as economically inside the body of a patient as by being kept in a medicine case at the office

Malaria and Uncinariasis

Dr W S Leathers, University, Miss Malaria and hookworm disease so devitalize the human body that typhoid and tuberculosis easily complete the destruction The insidious diseases must be stamped out. before any noticeable impression can be made on the diseases having a higher degree of mortality Teaching simple sanitation to the people is one of the great duties of public health departments I cannot understand why our government is spending millions to put water on lands in the West that will never be as productive as our lands of the South, and it will not give one cent to take the water off the land of the South Our richest lands are those which become covered with water

Immediate and After-Treatment of Railway Injuries

Dr. W W Grant, Denver The importance and necessity of immediate first-aid treatment in such cases is apparent by reason of the fact that these accidents are generally defined as contused lacerated and mangled and are much more prone to infection than smooth wounds The application of iodin hydrogen peroxid and alcohol pending the transfer of the patient to a permanent place of treatment is common Probing is seldom justified under any conditions It is dangerous to operate while the patient may still be suffering from the shock of an accident and many surgeons do not realize the value of proper reaction before operating. To add a physical shock to physical injury will generally prove hurtful to the patient. There is no more urgent field for skilled surgery than the treatment of mangled feet, hands and fingers Lacerated tissues are more liable to infection and heal more slowly than other wounds The sewing up of torn and lacerated wounds is a sure harbinger of infection. Such wounds will have to be opened up again Drainage tubes constitute the safest plan for the prevention of infection Scalp wounds are not generally attended by severe shock, and heal rapidly, but the most insidious wound is the small punctured fracture Every such wound demands early investigation, or serious results are liable to follow

Treatment of Malaria with Reference to Its Eradication

Dr T E Wright, Monroe, La In one of the hospitals used by a railway in North Louisiana, 747 cases of malaria among the railway men were treated during the years 1912, 1913 and 1914 Between Jan 1 and Nov 1, 1915, 249 cases of malaria have been treated The patients remained in the hospital from four to six days This short stay in the hospital was due to the intensive treatment given malaria cases This economic feature of intensive treatment and prompt results when applied to the whole malarial district of the South is a matter of much greater importance and should receive serious consideration on the part of medical men Intensive treatment of malarial patients must be employed in order to decrease the number of carriers The intravenous use of quinin, administered with proper care, in doses of 10 grains, in proper dilution, repeated in from eight to ten hours once or oftener, according to the case, is the type of intensive treatment that more nearly sterilizes the blood of malaria than any other method heretofore employed Fewer cases of recurrence will follow the intravenous use of quinin The discomfort through this treatment of the patient is slight or of short duration, not lasting over five or six minutes

The Sex Question in Public Health

Dr Isadore Dyer, New Orleans The sex question is essentially one of public health Facts, not preachments, are needed in presentation of the sex question to young men and women. Perhaps the public school would be a good place to teach sex hygiene, and the proper men and women can be found to tell the children about the things that every child should know

DISCUSSION

Dr. E H Martin, Hot Springs, Ark Children in public schools should be separated Segregation of sex is practiced in a Mississippi town in the public schools Co-education causes a boy to learn subservience to a woman, and he does not make a very good soldier in later years

Dr Allan W Freeman, Washington, D C I have been attending public health meetings for a number of years, and have never heard a frank and honest discussion of the sex question It is a question of health and should be treated as such

Syphilis Its Relation to Public Health

Dr. Lloyd Thompson, Hot Springs, Ark All affected persons should be registered and a heavy fine should be imposed on the physician for failure to report The marriage license should not be given to any one until he has been examined thoroughly and has withstood certain tests Employers should require a bill of health of every employee and should refuse employment to any person who will not submit to a physical examination If prostitution is permitted, it should be put under strict surveillance and regular medical examination

Health Conservation Through Life Insurance Companies

Dr J L Davis, Waco, Texas The life insurance companies of the United States have taken the lead in matters of sanitation and right living They have been advocating proper living and demanding it of their policy holders Tuberculosis is recognized by insurance companies as exceedingly infectious, and for many years they have made careful inquiries into the lives of applicants for insurance along this line They have gone so far as to ascertain whether the applicant has been associating with tuberculous people Typhoid fever is the arch enemy of insurance companies Next is alcohol, and the greatest temperance lectures of the age can be taken from the records of almost any life insurance company

Sanitary Preparedness

Dr Rupert Blue, Surgeon-General U S P H S, Washington D C The maintenance of sanitary preparedness is no less the duty of the individual than it is of the community It is not altogether easy to teach so convincingly that the layman will appreciate these things If the simple truths of sanitation are impressed on the plastic mind of the schoolchild, we gradually create a people in whom sanitary living is a habit. If by child hygiene we produce better and stronger men and women, these in turn will bring into the world stronger children, because they will have learned that mating with the weak and defective produces weak and defective children Thus we shall have a practical eugenic betterment

The impression I desire to leave in your minds is that, if America would avoid decay and retrogression, if she would be ready for the supreme trial of strength when the hour of calamity comes, she must retain her sanitary defenses at all times The sane and healthy nation, republic of healthy minds in healthy bodies, adding by its labors, uninterrupted by disease, to the material and spiritual welfare of the world, is prepared alike for peace and war

The Allen Treatment in Diabetes by Fasting

Dr. Isaac Ivan Lemann, New Orleans Allen believes that we have been wrong in trying to maintain or increase the weight of our diabetic patients when glucosuria persists, for such attempts simply keep the body at a size beyond the capacity of the pancreas to provide sufficient internal secretion for it. Better, therefore, to have the body thinner and have enough pancreatic secretion to do the work of a smaller body This pancreatic internal secretion he would have us conceive as an amboceptor binding blood sugar to the tissues When the amboceptor is lacking, the unbound sugar is secreted by the kidneys Allen's proposals are (1) to starve the patient until the urine is sugar-free, (2) to add gradualy to his diet until the point of tolerance of protein and fat, as well as of carbohydrate, is reached, (3) to remain within these points of tolerance, no matter how low they may be and no matter how thin the patient may be Attempts to increase the patient's weight by the addition of a large number of fat calories to the diet results in the return of the glucosuria My short experience with Allen's method, embracing now five cases, has served to free me of the fear of precipitating a severe acidosis by the sudden starvation, and, secondly, it has convinced me in one severe case of its great possibilities in certain cases at least The other four cases were mild Two of them I have tried in vain to make aglucosuric by gradual reduction of carbohydrate intake, then of protein intake, and finally in one of them by the interposition of green days These two patients became aglucosuric in twenty-four and forty-eight hours of starvation, respectively The other two mild cases required twenty-four and seventy-two hours' starvation, respectively In none of these four did acetone appear in the urine None of the patients had any serious complaints Not only was the disappearance of the glucosuria brought about more promptly and with less trouble both to the patient and to me than by the former technic, but also it was possible to build up these patients quite a livable diet and still maintain them aglucosuric In the two patients whose points of tolerance I had tried to determine by the older method, I found the new tolerance quite satisfactory and far in excess of what it had been prior to the past My brief experience with the method has been sufficiently satisfactory and enlightening to encourage me to proceed

Pyelitis in Infancy and Early Childhood

Dr L R DeBuys, New Orleans The majority of cases of pyelitis occur in children under 3 years of age, and of these most of them under 2 In from 90 to 96 per cent of the cases females are affected It is highly probable that much of the trouble in the adult female kidney may have its origin in the infections of the kidney during infancy and childhood Pyelitis may be primary or it may be secondary to a cystitis The treatment of pyelitis may be included under four heads (1) drugs, (2) irrigation of the pelvis by the direct method, (3) irrigation of the pelvis by the indirect method, (4) vaccines Many drugs have been advocated, among them hexamethylenamin, potassium citrate, methylene blue, creosote and salol Of these the first two are used most frequently Hexamethylenamin is best given early and in large doses, from 2 to 3 grains, every three or four hours, to a child from 1 to 2 years of age. By far the most reliable method of treatment in pyelitis in the small patient is by irrigation of the pelvis of the kidney by the indirect method By this is meant the giving of large quantities of liquids It is well to dilute their food so that they may be always hungry and in order to satisfy their hunger they must take large quantities of fluids to receive a sufficient quantity of nutriment Vaccines are sometimes of benefit and should be autogenous Their effect is not uniform and reliable but in some instances has been of advantage. They should be given in doses beginning with 50 000 000 and increasing rapidly to 200 000 000 or even 250 000,000, the interval varying from three to five days, depending on the reaction of the patient and the recovery from the reaction. In the resistant and chronic cases the autogenous vaccine is more especially indicated Should the vaccine not produce an immunity after from three to five vaccinations, as shown by the bactericidal property of the blood, its use should be discontinued

Dietetic Treatment of Bronchial Asthma

Dr. **Allan Eustis**, New Orleans A review of 178 cases justifies the following conclusions 1 Most cases of bronchial asthma are due to absorption of proteolytic toxins 2 These toxins may be absorbed from a suppurating accessory sinus in the nose or from the intestinal canal 3 Treatment of intestinal toxemia is as important as any drainage of focal infections 4 An alveolar abscess may be the focus from which the toxin is absorbed 5 In the dietetic management of asthmatics, animal proteins, with the exception of buttermilk should be eliminated from the dietary as much as possible

Influence of Potassium Iodid on Syphilitic Reaction

Dr. **Randolph Lyons** New Orleans That iodin is the essential factor in producing the positive reaction in a nonsyphilitic individual is demonstrated by the fact that hydriodic acid thyroid extract and possibly hyperthyroidism will produce a similar effect. When a luetin test is made, it is essential that no iodin in any form (potassium iodid) be taken internally Furthermore, it is important to know that iodin has not been ingested for at least three weeks previous to the performance of the test. Torpid or later reactions occurring after intervals of two weeks are usually due to the ingestion of potassium iodid The reaction may be influenced after an interval of two months by the subsequent administration of potassium iodid (Sherrick) Anomalous reactions may generally be attributed to potassium iodid Activation of the luetin test with mixed treatment vitiates it. Clinical differentiation between the two, luetin reaction and iodin reaction cannot be made with any degree of certainty When a positive test develops very rapidly an iodin reaction may be expected The extreme prevalence of the use of iodin in some form (potassium iodid) will necessitate a critical review of the published reports of positive reactions in order to eliminate the iodin reactions This will undoubtedly lower the percentage of positive results

Influence of the Injection of Blood on Anemia and Infections in Children

Dr. **J Spencer Davis**, Dallas Texas In the injection of whole blood we have the therapeutic means of increasing the number of white blood corpuscles In many cases a crisis in the disease can be brought on and the destruction of bacteria in the body is hastened We have found it of great value in the acute infectious diseases of children such as scarlet fever Like all other therapeutic measures, it sometimes fails where it is most needed, and its value is dependent on the ability of the individual to respond to the injection I have never seen any bad results following the injection, although at the site of the injection we have the same series of color changes which occur in an ordinary bruise

Scurvy Versus Rheumatism

Dr. **Dandridge P West**, New Orleans The prognosis of scurvy depends on the early recognition of the disease, severity of the symptoms and the complications Death in untreated cases results usually from hemorrhage exhaustion and bronchopneumonia In recognized cases, the treatment is highly satisfactory and none is more easily instituted It may be covered briefly by the rule Discontinue all previous feedings especially if they have been patented, boiled or sterilized, give fresh milk, fruit juices, and if the digestion will stand it, puree of potato or green vegetables In all suspected cases the effect of treatment, the therapeutic test, is of the greatest value, inasmuch as the results show in forty-eight hours, and no harm, as a rule, can be done by waiting so long If in doubt when the baby is unduly irritable on being handled, and shows perhaps local manifestations of joint pain preclude first the idea of rheumatism, change the diet to raw milk, and give orange juice

6 Study of Wandering Mesenchymal Cells on Living Yolk Sac and Their Developmental Products Chromatophores Vascular Endothelium and Blood Cells. C R. Stockard New York.

4 **Action of Tectorial Membrane**—According to Hardesty, the tectorial membrane is a vibratory structure and from its consistency, shape, proportions and position, is the chief vibratory structure in the cochlea It may vibrate in such a way that a modification of the telephone theory of hearing may be applied to it Sound waves of low vibration frequency produce vibrations in the entire tectorial membrane regardless of amplitude, while those of higher frequency produce vibrations in varying extents of it, depending on their amplitude Among the sound waves of the higher vibration frequencies capable of being appreciated, the extent or length of the tectorial membrane in which efficient vibrations may be induced depends more on the vibration frequency or pitch than on the amplitude of the sound waves The higher frequencies being damped out more readily than the lower, varying extents of the membrane are affected according to the vibration frequencies of the waves applied, the highest frequencies affecting the thin, basal end of the membrane alone Some evidences of what may be considered resonance in the tectorial membrane were indicated, but were thought questionably trustworthy as such No resonance of the form demanded by the Helmholtz theory is possible It is suggested that no resonance or analysis of sound is accomplished by the cochlea in itself other than such as may be possible in the evidences that, beginning with its basal end, different extents of the tectorial membrane may be thrown into vibration by different sound waves, depending on the frequency and amplitude of vibration It is admitted that waves of low frequency and high amplitude may induce vibrations also in less flexible and otherwise less adapted

basilar membrane as a whole Attention is called to the fact that its chief load, the spiral organ, increases in size in passing from the base to the apex of the cochlea and that this suggests a vibratory behavior possible in it similar to but not so comprehensive as that claimed for the tectorial membrane

24 *Management of Enuresis A Newlin, Philadelphia
25 Fatal Afebrile Nonparalytic Polioencephalitis Treatment by Autoinoculation with Spinal Fluid L C Ager, Brooklyn

22 **Rapidly Advancing Pulmonary Tuberculosis**—The case reported by Hall was evidently one of a common type of tuberculosis A pneumococcus infection of the respiratory tract occurred in a child with tuberculosis largely confined to bronchial lymph nodes, the tuberculosis spread rapidly throughout the lungs and body The Roentgen ray made evident early the tuberculous lesions eliminating the diagnosis of simple bronchitis, influenza infection or bronchopneumonia It showed the progress of the disease from the hilus into the lobes, most marked in the right lower and the appearance of a cavity before these were evidenced by physical signs The von Pirquet test gave a marked reaction early in the disease before the patient failed It was faint as the child became weaker and absent a few days before death Tubercle bacilli were not found until late in the disease, when the diagnosis was already well established Then they were found first in the stools, later in the sputum

24 **Management of Enuresis**—The method of management of enuresis, whether it be diurnal or nocturnal, or both, that has given Newlin the best results, consists in the simple procedure of anticipating the involuntary act by a voluntary emptying of the bladder This is the usual accompaniment of any treatment, but, Newlin says, when carried out systematically, can preclude the use of drugs absolutely, it gives far better results than when the chief reliance is placed on medicines with only perfunctory instructions as to the actual management of the child itself This method of handling even obstinate cases of enuresis is rarely carried out systematically, but when it is so conducted gives almost invariably successful results The chief obstacle encountered is the difficulty of impressing on the mother or nurse the fact that unless the instructions are absolutely faithfully followed the result is failure

The nurse is given a sheet of paper with the hours of the day and night placed in a vertical row at the left-hand margin under the heading of the day of the week. If the enuresis occurs on an average of every two hours, she is instructed to put the child on the chamber every hour for the first twelve hours If she finds the clothing wet at any such time the hour is noted on the chart At night the child is lifted almost as frequently during the early hours, that is, up to 11 o'clock or midnight, after that every second hour is usually all that is necessary for the first night At the end of the first twenty-four hours she then either has a clear chart or one with several hours marked as indicating the time of the enuresis On the second day she is guided by her chart of the previous day, and she may extend the length of time between the voluntary urinations, always, however, anticipating the hours marked as "wet" on the day before, placing the child on the chamber at least a half hour before the time indicated

29 Iconographic Notes on Girolamo Fracastoro A C Klebs, Baltimore
30 *Experimental Study of Factors Responsible for Noninfectious Bone Atrophy E G Grey and G L Carr, Boston
31 Origin of Lactic Acid Bacteria in Milk P F McGuire, Baltimore

26 **Calcareous and Osseous Deposits in Arachnoidea**—Cushing and Weed summarize the results of their study as follows Calcareous depositions in the form of psammoma bodies, or corpora amylacea of varying stages of development and of varying size, are of common occurrence in the arachnoidea of man and of the lower animals Associated with this process of calcification there is apt to occur a hyperplasia of the arachnoidal mesothelium The deposits of lime salts are apparently laid down in cell bodies and in this membrane can bear no relation to the blood vessels The occurrence of true bone formation in the arachnoid of man should be regarded as a similar phenomenon, except that one may consider the process of ossification to be proliferative rather than degenerative The so-called dural endotheliomas show histologically the same cellular arrangements with calcareous osseous depositions that are commonly found in the arachnoid and therefore take their origin in all probability from the mesothelium of this membrane

27 **Calcium Factor in Hemophilia**—Typical hereditary hemophilia is not associated with a deficiency to calcium Hess' investigations showed that the addition of calcium to the blood in vitro delays rather than hastens coagulation Furthermore, a deficiency could not be established by quantitative determinations of the calcium in the blood, and a metabolism study showed that the exchange of lime salts, as well as of numerous other inorganic as well as organic substances, differed in no way from normal

30 **Study of Factors Responsible for Noninfectious Bone Atrophy**—A destruction of the sensory nerves to a part according to Grey and Carr occasions no direct local atrophy of bone A destruction of the motor nerves, on the other hand, leads to a certain amount of atrophy This, however, is indirectly the result of inactivity of disuse and is directly proportional in extent to the degree of paralysis present in the part Local venous congestion leads directly to no recognizable changes in the structure of bone Local anemia due to injury to the arterial supply, except in an extreme degree, likewise occasions no bone atrophy so long as the part remains functionally active Inactivity atrophy may appear soon after immobilization of a limb—as early as the fourth or fifth day in rabbits It is probably due to a decrease or to an absence of the functional stimuli necessary to the normal nutrition of bone Immobilization retards the process of repair in bone injuries

41 Spontaneous Tumors of Liver in Mice—Twenty-eight primary tumors of the liver were found by the authors in 10,000 mice of all ages dying natural deaths and carefully necropsied but one other case is recorded in the literature All were liver cell adenomas one showing malignant structure and multiple metastases in the lung, two with malignant structure without metastases, and the remainder exhibiting all degrees from probable malignancy to simple adenomas No tumors of bile duct type were found Sarcoma-like growths were found in six, but these are more probably granulomas No hemangiomas or other tumors were found There were three carcinomas secondary to mammary gland tumors and three secondary sarcomas None of the tumors seemed to be the result of cestode infection of the liver or other evident cause. The coexistence of liver tumors with other primary tumors is high there having been multiple tumors in ten of the twenty-eight cases, in three of these both tumors were hepatic in the other seven different organs were involved Only six secondary tumors were found in the liver, three being from mammary gland carcinomas, one from a mesenteric sarcoma, and two secondary osteosarcomas

42 Influence of Roentgen Rays on Antibody Formation—The effect of exposure to Roentgen rays on the production of different antibodies is summarized by Simonds and Jones as follows (a) The formation of agglutinins is appreciably lowered, although not so markedly as in the case of rabbits injected with benzol (b) The attempt to study bacteriolysins for typhoid bacilli was less satisfactory than in the case of other antibodies The authors' results do not warrant a positive statement, but the indications are that the production of bacteriolysins for *B typhosus* in their animals was not greatly interfered with by exposure to Roentgen rays (c) The opsonic content and the complement fixing power of the serum roentgenized rabbits did not differ appreciably from that of control animals

43 Injections of Benzol on Antibody Production—In the experiments detailed by Simonds and Jones rabbits were injected subcutaneously with a mixture of one part benzol and two parts olive oil The doses were, as a rule, so adjusted that each animal received approximately 1 c.c of benzol per kilogram of body weight A depression in the production of hemolysins agglutinins and opsonins was evident in the animals injected with benzol as compared with normal controls injected with the same antigen The depression was *most marked in the case of hemolysins and* least so in that of opsonins

45 Bacteriologic Study of Septic Sore Throat—The epidemic studied by Krumwiede and Valentine occurred during June 1914 in Rockville Center, Long Island, a village of 4 250 inhabitants It was soon evident that the common element among the infected persons was their milk supply Out of 232 cases 205 obtained their milk from one dairy Streptococci similar culturally and identical in their agglutination were isolated from cases of septic sore throat and from the udder of one cow, showing no evidence of mastitis, except the peculiar character of the milk from one quarter The bacteriologic as well as the epidemiologic facts almost certainly show that the infection was primarily of human origin In tracing the source of such an epidemic, the authors point out that the efforts should be towards finding cases of sore throat among those engaged in producing the milk not mastitis in the cow alone. If human streptococci are found in mastitis they are most likely secondary agents in an already existing inflammation due to bovine strains The streptococci in different epidemics differ culturally and those similar culturally differ in their immunity reactions Cultural similarity of strains from man and cattle is insufficient to prove their identity Cultural identity in every detail or immunologic identity is essential

46 Method of Producing Tetanus Toxin—Anderson and Leake place on record the method of making tetanus toxin which has been used with minor modification at the Hygienic Laboratory of the United States Public Health Service since 1905 and, at the suggestion of the laboratory, in most of the establishments manufacturing antitoxin subsequently At the Hygienic Laboratory the toxin is prepared for the purpose of standardization of tetanus antitoxin in accordance with the American method while in the antitoxin establishments it is prepared for the active immunization of horses The important points in the method are the method of preparation, freshness, and reaction of the medium, the preliminary cultivation, and the growth without the use of oil vacuum inert gas, or pyrogallate—a great advantage, the anaerobiasis is attained by inoculating liberally into liter flasks immediately after steaming For details the original article should be consulted

84 Nonsurgical Treatment of Exophthalmic Goiter I Bram, Philadelphia
85 Chronic Constipation in Infants J Epstein, New York

78 **Sanitary Study of Condensed Milk**—The authors summarize the results of their studies as follows The value of sweetened condensed milk depends on the care and cleanliness used in manufacture There is a want of evidence that the bacteria or chemical constituents are capable of affecting the health Only the use of the best quality of sweetened condensed milk is to be commended in the feeding of infants Sweetened condensed milk, when carefully prepared from whole milk, has special indications as an infant food They may be thus expressed Many infants are unable to digest the fat of cow's milk, even when two or three volumes of water are added In such cases the half digested curds of casein are vomited The change in these circumstances to sweetened condensed milk allays the vomiting These facts are well established clinically Sweetened condensed milk has generally a constipating effect The opposite view that it produces diarrhea seems to be wanting in evidence Clinical evidence agrees with Finkelstein's observation that the intestinal irritation caused by milk is an effect of the action of the liquid portion, when freed of fat, sugar, and protein Sugar appears to have a food value superior to fat, as shown by Hellesen

14 Wound Infections and Their Treatment A E Wright

8 **Diagnosis of Paratyphoid**—Torrens and Whittington found that there are eight symptoms which occur in at at least 20 per cent of the cases at the onset In order of frequency these are 1 Headache (85 per cent) 2 Diarrhea (55 per cent) 3 Abdominal pain (35 per cent) 4 Aching pains in the limbs (30 per cent) 5 Shivering (25 per cent) 6 Extreme general weakness (25 per cent) 7 Backache (25 per cent) 8 Epistaxis (20 per cent) Headache is usually vertical in distribution, though a migrainous type, especially severe behind the eyes, has been present in several cases of para A Abdominal pain is rarely severe or colicky and is usually generalized, and does not often last more than two or three days The initial diarrhea is rarely severe, being usually limited to three or four loose stools per diem Pain other than abdominal pain or headache is usually referred to the back or limbs Extreme general weakness is often sudden in its onset, and sometimes this and headache are the only symptoms Epistaxis is rarely volunteered by the patient as one of his symptoms While shivering is liable to occur in the course of any infection with the liberation of toxins or bacteria into the blood stream, yet the occurrence of repeated shivering attacks seems of special significance of the onset of paratyphoid This is especially true of paratyphoid A, in which onset, and in which it is liable to occur with rigors throughout the disease

Cough is complained of in nearly 20 per cent ,of the cases, and seems more common in para B, but is rarely troublesome Vomiting is far more common in paratyphoid than in typhoid This is especially so in para B cases, in which vomiting occurred in 17 per cent Dizziness and deafness occurred in 7 per cent of all cases Sore throat or hoarse voice as evidence of laryngitis or pharyngitis occurred only in 5 per cent of the cases, all those being cases of para B Temperature during the onset Patients in whom the onset was rapid have said that their temperatures were 102 to 103 when first taken Cases which have started in a hospital in which the patient was being treated for some wound, and in which the temperature was being taken as a routine measure show a rapid rise, the maximum usually being reached in forty-eight hours It seems fairly certain that the 'step-ladder' rise so frequently seen in typhoid is far from common in paratyphoid During the second week, in the average patient, the temperature ranges between 99.2 and 102.4 Of the cases analyzed 60 per cent showed this remittent type of fever, while about 20 per cent were intermittent A really steady temperature in the second week was only seen in 5 per cent of the cases, 70 per cent of all cases of para B and 40 per cent of para A are of twenty days' duration or less In about 30 per cent of all cases of each form the pyrexia lasts fifteen days or less In the average case the temperature in the second week and at the beginning of the third week does not reach as high as 103 Only about 35 per cent of all cases of paratyphoid ever reach 103, and only about 12 per cent reach as high as 104

The pulse is one of the most important aids in diagnosis The rate is uniformly slow as compared with the temperature A temperature of 102.5 with a pulse of 70 is characteristic and is more than significant of a group infection Without any apparent change in the general condition, the rate may be at one time 65 and at another 85 or 90, and, curiously, a high temperature may coincide with a low pulse rate and vice versa The quality of the pulse is characteristic and important There is a most marked softness or compressibility present The blood pressure in a small series of cases examined with the sphygmomanometer was found to vary from 80 to 100 mm Hg Spots are present in as many as 75 per cent of all cases at some time during the disease They appear in crops, and last three or four days, as in typhoid The spleen is either palpable or enlarged to percussion in nearly 60 per cent of cases, it can be felt in about 35 per cent of all cases some time during the course of the disease Examination of the heart is negative Examination of the lungs will show bronchitis in less than 30 per cent of the cases The central nervous system shows no constant abnormality

10 **Typhoid Plus Paratyphoid A Plus Paratyphoid B Plus Cholera.**—The number of individuals inoculated by Castellani and Mendelson with the tetravaccine amounts to 50,000 and more than 120,000 by colleagues The reactions were usually mild and consisted usually of a small area of redness, a slight local temperature and some tenderness General reactions were seldom complained of, and when inquired into revealed a slight headache and a general inaptitude These particulars were carefully looked into in all cases on the second inoculation The left arm is chosen, the skin over the insertion of the deltoid, and a quick stab, as though one were shaking a drop of ink from a pen results in placing the point of the needle at the exact depth The syringe is held in the right hand between thumb and index finger, while the tip of the ring finger is placed just above the point of the needle, acting as a check to the force applied No after-treatment, as massage or sealing the puncture, is used

The authors examined the blood of more than 100 individuals inoculated with the tetravaccine for agglutinins The individuals inoculated with the tetravaccine produce a large amount of agglutinins for typhoid, a fairly large amount of agglutinins for paratyphoid A and paratyphoid B, a certain amount for cholera, which varies between the limits 1 20 and 1 150 Comparing the results with those obtained in control individuals inoculated with typhoid, paratyphoid A, paratyphoid B and cholera the amount produced is not distinctly smaller There was no septic or other accident in any of the more than 50,000 men the authors have inoculated, this entailing more than 100,000 injections, nor any untoward accident observed by colleagues who inoculated in Serbia more than 120,000 men with the tetravaccine The inoculated persons develop protective substances for the four germs typhoid, paratyphoid A, paratyphoid B and cholera

15 Wound Infections and Their Treatment. A E Wright
16 *Nervous Affections of Sixth and Seventh Decades of Life J M Clarke
17 *Gunshot Injuries of Peripheral Nerves W Harris
18 Gunshot Injuries to Peripheral Nerves R H J Swan
19 Cases of Tetanus Like Spasm Localized to Wounded Limb R D Rudolf
20 Case of Oral Sepsis. A Abrahams.
21 Zinc in Potable Water J C Thresh

16 **Nervous Affections**—Turning to those affections more purely of nervous origin, Clarke says that the period from 50 to 70 compares favorably with that of either childhood and adolescence or the age from 25 to 50 In both the latter periods of life falls the incidence of the nervous diseases due to infections and intoxications from which the age after 50 is mostly exempt The main period of onset of the hereditary and familial diseases, those included under Gowers' designation of abiotrophy, occurs in childhood and adolescence while from 20 to 50, together with some tabiotrophic diseases whose onset is late, the nervous affections due to syphilis and alcohol are rife After 50 the chances of the occurrence of cerebrospinal syphilis are comparatively slight Lastly, the purely nervous diseases which are especially characteristic of this period of life are paralysis agitans, some of the combined scleroses of the spinal cord and certain muscular atrophies of central origin Clarke suggests that it is possible that some of these affections owe their origin to that process of premature senescence or defective vital endurance of certain neuronic systems known as abiotrophy, and that this pathologic process may occur at any age Paralysis agitans especially, in its narrow age incidence, uniformity of symptoms, progressive character and occasional familial tendency, suggests this mode of origin

17 **Gunshot Injuries of Peripheral Nerves**—The following is a summary of the points made by Harris The importance of an accurate history of the details of the wound or wounds and of the immediate effects A careful and methodical examination of the paralysis, both motor and sensory is necessary to determine whether it matches with the known anatomic distribution of one or more nerves, or of a portion of a plexus, or whether it resembles the phenomena produced in hysteria Careful charts of the sensory loss are more important than the presence of complete muscular paralysis with reaction of degeneration, in estimating the severity of the injury of a mixed nerve The various stimuli used in testing by hard or light pressure, pin-prick, scratch camel-hair brush or cottonwool, are tests of different system or fibers Hard pressure will still be perceived except in total interruption of the nerve conductivity by actual division or by its inclusion in dense scar Commencing recovery of sensation may in some cases be observed within a few days only of secondary suture of the nerve Variations, however, in the sensibility must be allowed for, as this may vary from day to day within narrow limits, or according as the limb is warm or cold

18 **Gunshot Injuries to Peripheral Nerves**—Swan has seen 63 cases of gunshot injury to peripheral nerves Of these cases 38 were operated on, involving the exploration of 41 individual nerves, for in 3 cases the injury involved two distinct nerves Of the 25 patients not operated on, 6 refused any operative treatment for conditions in which it was practically certain that a nerve was badly injured, in 3 it was deemed inadvisable to attempt any operation, and in 4 cases operation has been deferred until such time as the wounds made by the bullet have healed In the remaining 12 patients gradual improvement and recovery to function returned after an interval varying from two to twenty-four weeks after the injury Swan says that unless the symptoms point to a partial injury to the nerve he knows of no point to distinguish between complete nerve division and involvement in dense scar tissue He has operated on cases in

which there have been complete anesthesia and paralysis of the muscles supplied by the nerve and with complete reaction of degeneration, but in which he found the nerve undivided, but densely fixed by scar tissue to surrounding structures The anatomic lesion is of small moment, however, as operative treatment is required in either case, and the sooner it is done when asepsis can be guaranteed the better the prognosis for the patient In cases of complete nerve division there is no question of the procedure to adopt —the ends must be dissected free, the bulbous proximal end removed until nerve bundles can be seen, a small part of the distal end resected, and the two ends accurately joined tension on the nerve being relieved by stretching the nerve and by suitable position of the limb In cases in which the nerve is firmly involved in scar tissue, and which on dissection is found to be dense and thickened, the best thing to do, if nerve will allow, is to resect the fibrous portion and join the two ends by accurate suture

Bulletin de l'Académie de Médecine, Paris

October 19 LXXIV No 42, pp 429 463

22 *Diagnostic Importance of the Modifications in the Tendon Reflexes Under the Influence of Chloroform J Babinski and A Fremont.
23 The Children Born from Rape (Le viol de guerre et la protection de l enfance.) H Henrot
24 *Intubation to Maintain the Circulation in Wounded Artery (De l'intubation dans les plaies des grosses artères) T Tuffier
25 Bacteriologic Examination of Beer (Les bieres des Flandres) L Roussel and Others

22 **Differential Importance of Modification of Reflexes by Chloroform**—Babinski says that the works published on this subject to date discuss merely the physiologic behavior of the reflexes under the influence of chloroform He and his co-worker, on the other hand, present evidence to show that the behavior of the reflexes has differential importance in abnormal conditions It affords an objective means of distinguishing between actual nervous disease and hysteria, for one thing, and between different forms of nervous disease In six wounded soldiers whose cases are described in detail, the asymmetric accentuation of the reflexes, their asymmetric disappearance and asymmetric reappearance, confirmed the assumption of organic disturbance The survival of the elective exaggeration of the tendon reflexes, even during the phase of relaxation of the muscles, reveals the extent of the disturbance in the central nervous system resulting from the peripheral lesion It explains the tenacity of the disturbance and its clinical importance, justifying the patient's complaints and the functional disturbances, when otherwise there might be suspicion of malingering

36 War Wounds of Larynx and Trachea Guisez.
37 The Ear and Traumatisms of War (Appareil auditif et traumatisme de guerre) M Grivot

31 **Decalcification of Bones in Paralysis**—A number of typical cases are described and illustrated The findings are tabulated in 15 cases of paralysis of the hand without any signs of neuritis, also in 4 of paralysis from a direct wound of the brachial plexus, 3 of the ulnar, 4 of the median, 2 of the radial and 2 involving both ulnar and median nerves Decalcification was evident in all the groups, and hence it cannot be regarded as a sign of a lesion of any nerve, as it was often as pronounced in the neuropathic and hysteric cases or after immobilization for fracture as when the nerve had been severed The latter alone may entail osteoporosis, but it is equally liable to develop from the lack of exercise during immobilization, from disturbances in the circulation in the region, or from a constitutional predisposition It occurs in the same way as wasting of muscles or local sweating or hyperkeratosis in cases of disuse of a member from any neuropathic or organic cause

34 **Injuries of the Eyes in War**—Terrien discusses the direct injury of the eyeball or orbit or both from projectiles, indirect injury from a wound near or from the shock of an explosion without direct injury of the tissues, and, finally, visual disturbances of psychic origin A number of illustrations are given to illustrate technical points in repair In one of the cases illustrated a flap was taken from the thigh to make a new culdesac, permitting the wearing of an artificial eye In some cases men knocked down by an explosion, without direct injury, were totally blind when they regained consciousness and some could not hear and others had aphasia In others both vision and hearing were slightly impaired He has encountered eighteen cases of these visual disturbances Vision began soon to improve and gradually returned to its former status except for some slight reduction of visual acuity and difficulty in focussing objects The immediate blindness is evidently the consequence of the concussion from the explosion and conditions progressively right themselves When the disturbances drag along without tendency to improve, a psychoneurosis may be assumed and treatment instituted on this basis

39 **Hemophilic Joint Affections**—Du Pan relates that a boy of 15 was brought to the hospital on account of a very painful tumor of the ankle which seemed to be a sarcoma on the point of ulcerating, except that sarcomas are not so agonizingly painful The tibia was not tender, and although there were local heat and fever, yet there was no involvement of glands, no lymphangitis or fluctuation A small incision brought dark blood but no pus, and the little cut bled continuously for three days, confirming the final assumption of hemophilia Under calcium chlorid and diphtheria antitoxin the oozing of blood was finally arrested His family showed the usual skipping of the second generation and reappearance of the hemophilia in the sons of the daughters, three of the five sons being pronounced hemophiliacs

In treatment, the main thing is to suspect the hemophilia instead of taking the joint trouble for acute articular rheumatism or a tuberculous process, as is too often done Du Pan declares that this error in diagnosis has often proved fatal, he cites various cases in which puncture of the joint for supposed hydrarthrosis has caused bleeding to death In Poncet's case, the fatal hemorrhage followed application of the actual cautery at several points König has reported two cases with fatal outcome after resection of the knee, and the list is a long one of these sad blunders in diagnosis

The blood accumulating in the joint causes sudden pain and swelling and the limb is held as in acute rheumatism The region feels hot and there may be fever, but the skin keeps its normal color throughout the whole trouble There are, as a rule, several successive attacks involving different joints, but mostly the knee or elbow, one at a time, with or without some slight local trauma preceding The hemarthrosis may be entirely absorbed, but usually it persists and irritates the joint, with chronic arthritis as the result In the second phase this arthritis resembles in every respect a white swelling, there is thickening of the synovialis, impotence of the limb and wasting of muscle The pain is less in this stage, the swelling becomes more general, and the culdesacs are distended, but the local heat does not increase There is elastic fluctuation in the synovial culdesacs, as with a tuberculous process, and partial ankylosis develops After the inflammation has subsided, insidious destruction may continue, but there is never an abscess or fistula and never any enlargement of glands from hemophilia alone The sudden onset excludes malignant disease but hematomas in muscle may be taken for cold abscesses and incision lead to fatal hemorrhage Submucosa hemorrhages in pharynx and glottis in a second case reported were mistaken for Ludwig's angina or diphtheria In Du Pan's first case, a subperiosteal hemorrhage, the length of the thigh had been mistaken for phlebitis Hemophilic hemorrhage in the stomach has often been treated as for a bleeding ulcer, and, from the lungs, for pulmonary tuberculosis

The family antecedents and tests of the coagulating power of the blood will reveal the tendency to hemophilia Its first manifestations generally appear before the age of 2 and the hemophiliacs generally outgrow the tendency by 22 It very rarely happens that a hemophiliac succumbs to hemorrhage after 22 The most threatening hemorrhages are generally during teething or puberty Fatal epistaxis carries off fully 50 per cent of the hemophiliacs Others have succumbed to hemorrhage from the gums, lungs, kidneys etc , two brothers died from conjunctival hemorrhage The skin covering a hematoma is stretched shiny, and bluish or black, with a peripheral red zone These hematomas never suppurate but the blood coagulated in them may undergo calcareous infiltration The literature on hemophilia and theories as to its mechanism are discussed in detail

Horse serum to date has proved more effectual than anything else in treatment of hemophilia but its action is only transient Keller found that the coagulation of the blood in women did not seem to be affected by removal of both ovaries so that the lack of ovarian secretion cannot be the primary cause of hemophilia Ovarian treatment has been tried but with no appreciable results With a recent hemarthrosis immobilization and compression with a cotton pad protect the joint and favor absorption When the coagulating time has been reduced by general treatment it may be possible to incise and remove the clots distending the joint and thus ward off chronic arthritis In the chronic stage we are disarmed No one is justified in operating to correct deformity or ankylosis in a hemophiliac unless he has reached adult age, and it has been ascertained that the blood coagulates in an approximately normal manner In hemophiliac families the children should not have their teeth pulled but vaccination has never been known to bring on hemorrhage The hemophiliac should select a sedentary occupation

53 * Scrofula' in Adults. (Zur Skrofulosefrage) A. Bauer

48 **The Appearance of Immature Leukocytes in the Blood**—Photakis tabulates the blood findings in thirty-two cases of various acute infectious diseases to call attention to the importance for the prognosis of the appearance of immature leukocytes in the blood He found the immature forms numerous in five eighths of his cases, and these were all the severer ones This finding shows the toxic action on the bone-marrow of the infectious agent, and thus serves more or less as an index of the intensity of the intoxication The irritation of the bone marrow is manifested first by a neutrophil leukocytosis without immature forms, then metamyelocytes appear, then, along with them appear myelocytes and promyelocytes, indicating the progressive phases of the irritation In the severer infections, especially with sepsis all the immature forms are encountered, down to myeloblasts as in the leukemic blood picture The internal nuclear structure of the immature cells takes the stain differently from ripe cells, it is amblychromatic instead of the trachychromatic structure of the nucleus of the maturer cells By the response to Pappenheim's staining technic (May — Grünwald — Giemsa) it is possible to differentiate each cell according to its age and maturity, and thus estimate to a certain degree the severity of the infection

50 **Alcoholic Polyneuritis**—The neuritis was accompanied with paralysis of the diaphragm and vocal cord on left side The patient was a robust hotel-keeper of 29, and the nerves affected with paralysis were those which run along together in the neck on the left side Nothing could be found to explain this localized paralysis except alcoholism, the attenuation of the reflexes and the reaction of degeneration indicated a peripheral nervous trouble The paralysis of the phrenic nerve rapidly subsided The diaphragm was soon working properly, but the paralysis of the left vocal cord radial and peroneal nerves persisted for some time, but finally all retrogressed to a complete cure, except that there is still some slight paresis of both peroneal nerves This prompt recovery is of special interest as, usually, polyneuritis involving the vagus and phrenic nerves is considered very dangerous on account of the danger of fatal arrest of respiration

51 This article was summarized recently, November 6, page 1686, when it appeared in a Scandinavian journal

53 **"Scrofula" in Adults**—Bauer protests that the clinical picture which used to be called scrofula" is by no means restricted to children It occurs comparatively often in adults but unfortunately it is seldom diagnosed, and it fails to get proper treatment He has encountered adults with the typical cheesy glands in the neck and eczematous conjunctivitis, who were past 50 and had never had their lungs examined Knowledge of the possibility of scrofula in adults is especially important for lung specialists He refers in particular to the article by Schelble, on scrofula," reviewed in these columns page 1683, abstract 71, which makes no mention of scrofula in adults

54 **To Strengthen Unilateral Weak Vision**—Heine relates that a reliable and intelligent man, now 57, as a child could read only the headings in the newspaper with one of his eyes The other eye was apparently normal, and he found that he could see better with the weak eye by looking through his partly closed fist By systematically exercising the eye in this way, vision materially improved and the benefit was permanent Bandaging the better eye for a few hours each day is also liable to strengthen the weak vision in one eye, Heine has witnessed the transformation of unilateral strabismus into the alternating form in children In one boy of 8 tenotomy was done on the right eye for convergent squint Vision in this eye had been 1/30, but in a week it was 1/4, and in another fortnight nearly normal, but in binocular vision it was still defective In a large number of cases of supposed congenital weakness of vision in one eye, he found that the eye could see better through a narrow opening or slit In many the visual acuity increased from 6/30 to 6/18 by the use of the slit, and he thinks that systematic exercises of this kind might yield material benefit The stenopaeic hole or slit may help more than the best glasses, especially with congenital amblyopia He relates a few typical cases and expatiates on various technical points to bear in mind

65 **Adhesion of Nerve or Brain to Cicatrix Factor in Neuralgia and Traumatic Epilepsy**—Witzel long ago pointed out that the agonizing neuralgia after amputation was due to cicatricial incarceration of the end of the nerve The nerve should be divided high enough up to prevent this being possible His experience with wounds of the skull shows similar conditions here, the cicatricial tissue grows to the brain and induces traumatic epilepsy or headache This can be avoided or cured by separating the brain tissue and pushing it down, cutting out the cicatricial tissue at the site of the wound, and introducing a flap of fat under the dura as a cover to protect the brain He gives three illustrations of the exact technic The surface of the brain is smoothed off, but without extensive extirpation of the cicatricial tissue The flap of fat is taken from the thigh and it is cut twice as large as the gap in the skull, so it can be pushed far back under the skull all around, between the brain and the dura The fat side is turned toward the brain, the fascia side upward No attempt is made to fill the gap in the skull by a plastic operation, in fact, this would militate against the success of the encephalolysis

68 **An Imperative Warning to Physicians and Surgeons**—Heidenhain relates that from his student days he has always heeded Billroth's warning that in case of an operative infection the poison is much less apt to spread if the limb is kept perfectly still He has cut and scratched himself at operations numbers of times in the course of his long practice, but has never had any ill effects from them, as he has always made a point of wearing the arm in a sling for twenty-four or forty-eight hours, with a small moist compress over the wound to keep it from sticking He always gave up all work during this time and had others help him to dress and undress, and even help to feed him He escaped all ill effects so constantly that he began to think he was immune Not many years ago he dressed a small operative cut on the hand of a young pathologist and tried to impress on him the necessity of refraining to use his arm for two days Heidenhain then left town for a week, on his return he learned that the young man was dead He had worn the sling for half a day and then had gone swimming A chill that night was followed by fatal sepsis

Heidenhain's recent experience has confirmed him still more irrevocably in his conviction of the imperative necessity for absolute repose for the limb in these cases He cut his middle finger a trifle in operating an empyema The cut did not go below the papillary layer of the skin and he kept his hand in a sling in going his rounds, but that evening, pressed with work, he used the typewriter for an hour The spot became painful then and the next morning a subcutaneous phlegmon developed, requiring extensive incisions, and three weeks elapsed before it healed and three more before function was regained His many years of freedom while he kept the injured limb still, and his serious trouble the one time he failed to keep it still, testify to the soundness of Billroth's advice to keep the limb immovable for two days

78 Pharmacist Protests against Restrictions on the Dispensing of Certain Potent Drugs without a Prescription (Die Vorschriften über die Abgabe starkwirkender Arzneimittel) (Editorial)

76 **Restrictions as to Advertising of Proprietaries**—The military authorities in the state of Hannover have issued a decree along much the same lines as our *Pure Food and Drugs Act*, so far as the advertising is concerned Our exchange quotes the decree with approval and then also asks why such a decree is promulgated and enforced only while the state is under martial law Each of the provisions, it emphasizes, is fully as much to the advantage of the public health during peace as during war times

77 **The Manufacturing Chemists and the Medical Profession**—Two advertisements which recently appeared in German newspapers are reproduced with the comment that they afford opportunity for congratulating the medical profession anew on the high opinion held by the manufacturing chemists of professional honor among physicians

The first reads "Physician Wanted A remunerative and convenient country practice with sickness insurance societies is open in southern Hannover for immediate possession to young physician who gives the preference to the original preparations of manufacturing chemists"

The second reads "Physician Wanted What physician, one with the title of professor preferred, will father a new pharmaceutical tested by physicians with good results?"

Our exchange remarks that the fact that such demands can be publicly voiced suggests that there are in our ranks some black sheep who will stoop to dally with the sordid writers of the first advertisement, or father the child in the foisting procedure aimed at in the other

80 **Vaccination Against Dysentery**—There was a mortality of 19 4 per cent in the sixty-seven cases of dysentery in a small town, all in about one month Then all the sick were sent to a special hospital Search was made for carriers in the infected houses and several were found and sent away also All the adults left were inoculated with a polyvalent vaccine, a total of 342 persons out of a population of 800 About 243 were inoculated twice The reaction was always mild, generally merely a little local redness, swelling and painfulness A few had headache, and there was diarrhea for a few days in some In exceptional cases there was a little fever, with a chill, the day of the inoculation The fifty one children over 4 years old, in the infected houses, were all given an injection of polyvalent immune serum The epidemic was promptly arrested

82 **Typhoid Gastritis**—Plaschkes examined the stomach content after a test breakfast in large numbers of soldiers with typhoid restricting his research to those whose fever had subsided He found evidences of severe gastritis with impairment of motor functioning and digestive power in all but 4 In only these 4 of the total 14 with pronounced gastritis was the acidity normal, in 3 there was no free acid and in 7 it was abnormally low One had severe urticaria and all had abnormally large amounts of mucus He examined the stomach content from numbers of other patients with dysentery or paratyphoid, finding conditions in regard to the acidity practically normal There is reason to assume, therefore he says, that the gastritis of typhoid is peculiar to this disease Tests of typhoid bacilli in vitro showed that their proliferation was checked by gastric juice On the other hand the finding that the overwhelming majority of typhoid patients have a specific gastritis, persisting into convalescence is surely an indication to supply such patients with the lacking acid and the diet should be that given in other forms of gastritis in small frequent meals The rapid progress in his cases when food of this kind was given, with hydrochloric acid confirms the practical importance of these views They also suggest that infection does not necessarily always occur through the stomach Typhoid preceded cholera in 44 cases recently reported by Walko, but no instance is known in which typhoid followed on cholera In prophylaxis of cholera therefore the systematic giving of hydrochloric acid far into convalescence of typhoid may prove important.

87 *The Transperitoneal is the Preferable Technic for Cesarean Section (Extraperitonealer oder transperitonealer Kaiserschnitt?) K. Baisch.

87 **Cesarean Section in the Cervix**—Baisch relates that none of the eleven women whom he has delivered by extraperitoneal cesarean section behaved afterward as if there had been a laparotomy There was no tendency to paralysis of the bowels Recovery was amazingly simple and rapid in comparison to the convalescence after classic cesarean section In a twelfth patient he renounced the extraperitoneal technic because the woman had been laparotomized twice once for extra-uterine pregnancy and once for postoperative hernia In another case sterilization had to be done In both these cases the incision was low in the cervix, opening up the peritoneum widely Recovery was simple and rapid in both, as also in the seventeen following cases of transperitoneal cervical cesarean section

The incision, 10 cm long is made on the linea alba, through skin and peritoneum, and the uterus is opened on the median line in the thin and stretched lower segment No attempt is made to separate the bladder, or to make the incision in the peritoneum transverse, or to loosen up the peritoneum If necessary to tampon the uterus, after extraction of the child, the tampon is brought out through the vagina No attempt is made to drain the abdominal cavity either through the abdominal wall or the vagina The distended uterus holds the intestines out of the way so they do not present at all, and any fluids from the uterus are soaked up by two flat sponges wrapped in gauze compresses and worked down between the uterus and the abdominal walls The incision in the uterus is reenforced double with peritoneum sutured over the uterus suture, and this is covered with omentum This prevents any escape of uterus contents into the abdominal cavity By making the incision in the uterus in the most stretched segment, the coaptation and suturing of the thin walls proceed with special ease, and during the involution of the organ there is no traction or pulling aside of the walls The fold of peritoneum in that region is so voluminous that it can be laid in a double fold over the suture in the uterus wall, there is not such an excess of peritoneum in the fundus region, so this is impossible elsewhere Conditions therefore permit as simple and rapid recovery as after the extraperitoneal technic

Only thirteen of the total nineteen cases treated by this transperitoneal technic were "clean" cases The others had been repeatedly examined by midwife or obstetrician, without gloves and in several the membranes had ruptured twelve, twenty or twenty-four hours before Two of the women were already slightly febrile and the fluids in the uterus were fetid Labor had dragged along for days in many cases, in two primiparas of 40, seventy hours had elapsed since the birth process had begun, and with several others, thirty or forty hours had elapsed In every instance the puerperium was normal in every particular, although the conditions were in many of the cases less favorable than in the extraperitoneal series In the two febrile cases, perforation of the living child had even been contemplated The children were all delivered alive but one died from an intracranial hemorrhage, the operation had evidently come too late in this case No high forceps, prophylactic version, premature delivery or a pelvis enlarging operation was required in any of the cases The operation was done on account of contracted pelvis, rigid birth passage in elderly primiparae, cicatricial atresia of the vagina, etc Eight of the women were allowed to leave the clinic the tenth or eleventh day The transperitoneal technic thus proved to have all the advantages of the extraperitoneal method and to surpass it in some respects

104 *Treatment of Sciatica with Rectal Saline Infusion by the Drop Method N A Gubin

99 **Action of Peptone on the Heart, Vessels and Blood Pressure**—Pissemsky studied the action of peptone on the isolated heart, coronary vessels, peripheral arteries, and the vessels of the isolated intestines and kidneys of rabbits He used mostly Witte's peptone, but also peptone prepared from albumin and blood The substance was passed through the vessels in solutions of 1 200, 1 1,000 and 1 10,000 The latter two solutions caused weakening of cardiac contractions, while stronger solutions (1 200) stimulated the heart to contract, the cardiac rhythm remaining uninfluenced Strong solutions (1 200) also produced marked dilatation of the coronary arteries The same occurred, but was transient, with weaker solutions, or the weaker solutions showed no effect The action of the peptone on the peripheral vessels was studied on rabbit's ears with the method of Kravkoff The action was vasoconstricting with all concentrations and with any kind of peptone However, the arteries of isolated intestines showed dilatation from large doses, but weak solutions had no effect Somewhat similar was the action of peptone on the vessels of the isolated kidney The blood pressure (0 5 gm peptone to one kilogram body weight) either remained unchanged, or rose, contrary to what may be observed in dogs in which the same doses cause a fall in the blood pressure

100 **Multiple Neuritis from Tapeworm**—Leporsky collected from the material of the University clinic of Dorpat sixty-four cases of tapeworm *(Bothriocephalus latus)* observed in five years Of these sixty-four cases, fifty-one showed more or less marked involvement of the nervous system in the form of polyneuritis, which in 14 per cent of the cases was severe He gives histories of three cases of polyneuritis in which no other explanation for the polyneuritis except this parasite could be found With the expulsion of the worm there was immediate improvement Leporsky is of the opinion that a toxin is formed in the intestines, whence it penetrates into the nervous system, causing various central and peripheral nerve disorders, such as chorea, epilepsy, neuralgia, and multiple neuritis A polyneuritis of this etiology might be called "enterotoxic polyneuritis" Sometimes no definite nerve symptoms are produced, but merely general complaints of weakness, and of pain in the joints and muscles These symptoms are usually taken for rheumatism, when they are in reality due to the presence of the tapeworm With the expulsion of the latter these rheumatoid pains disappear at once

101 **Serum Sickness and Allied Phenomena**—Molchanova found so-called serum phenomena, such as urticaria, fever, adenitis, etc, in 56 7 per cent of the patients given diphtheria antitoxin, and in 64 3 per cent of those treated with antistreptococcus serum for scarlet fever In those cases in which the antitoxin or serum for scarlet fever had been injected more than once, such phenomena were present in 100 per cent, but when the antitoxin was injected for the first time, complications were noted in 47 5 per cent and in 59 6 per cent in the scarlet fever cases The first sign of the serum disease was swelling of a gland in the inguinal region, as the serum was usually injected in the abdominal skin or in the gluteal muscles The adenitis very seldom appeared in the axilla or neck, and it was the latest of the serum phenomena to disappear The most frequent sign, however, was a rash in the form of urticaria, erythema multiforme, measles-like, scarlatinaform or hemorrhagic The latter was found in 2 2 per cent after diphtheria antitoxin and in 10 4 per cent after antistreptococcus serum injections

Of other rarer complications, Molchanova mentions affections of the joints (arthralgia, synovitis), elevation of temperature and albuminuria (in 0 3 to 0 4 per cent of the cases) and edema of the face, lids, upper lip, scrotum and prepuce The edema was not associated with albuminuria, casts or increased blood pressure, rather was there a fall of the latter A very disagreeable complication was gastro-intestinal disorders, vomiting, diarrhea and abdominal pain In four cases only there occurred cardiac collapse, with one death All these complications occurred usually from seven to twelve days after the injection of serum, or if the patient had had an injection some time before, the interval was from one to five days Concentrated serum gave fewer complications Calcium chlorid (2 per cent solution, a teaspoonful three or four times daily) did not prevent occurrence of complications The anti-anaphylactic method of Besredka was used in fifteen patients (2 c c of antitoxin was injected intramuscularly, followed two or three hours later by the curative dose hypodermically or intramuscularly), but it did not prevent complications The latter were rather mild, however, and hence Molchanova warmly recommends this method

102 **Intestinal Digestion in Man After Excision of Large Portion of Lower Intestine**—Gurevich has been studying the extent of assimilation of alimentary substances in a man who had had 159 cm of ileum removed He found that only the carbohydrates are normally assimilated, nitrogen and fats, very poorly Instead of the 12 1 per cent which is the normal rate for unassimilated nitrogen, there was 48 15 per cent The tests were carried out seven months after the operation, during which time the carbohydrate metabolism had become normal, that of albumin and fats was still deficient Yet the patient was gaining in weight and was cheerful, though he still had persisting diarrhea

103 **Cholera and Amebic Dysentery**—Yakimoff and Demidoff recommend to examine suspicious cholera cases, during epidemics in tropical regions, not only for cholera vibrios, but also for ameba It is necessary to stain the latter (Giemsa), it is easy to find them then There may be a combined infection with amebic dysentery and cholera

104 **Saline Infusion in Treatment of Sciatica**—Gubin obtained excellent results in the treatment of sciatica with rectal injections of salt solution (1 4 teaspoonful sodium chlorid to two glassfuls of hot water) with the drop method He used this method in seven patients and all recovered The general reaction was profuse sweating and increased diuresis A detailed report of one case with the description of the method, and illustrations, is given

THE KINETIC DRIVE

ITS PHENOMENA AND ITS CONTROL *

GEORGE W CRILE MD
CLEVELAND

INTRODUCTION

The species of animal now dominating the earth more completely than any other is at this moment in a state of abnormal activity — the back-wash of the European war is seen in the quickened pulse everywhere even in this land Not only in war, but in peace also, the complicated machinery of civilization created by man often drives him to his own destruction Nowhere is this industrial and commercial driving more intense than in this city It has occurred to me, therefore, that it might be interesting to attempt an analysis of the mechanism by which this speeding is accomplished, and relate it to the speeding which is due to other stimuli such as infections, autointoxication, physical injury, etc Since the process of speeding is identical with that of the transformation of potential into kinetic energy, the state of increased energy transformation might fittingly be called the *kinetic drive* To facilitate discussion I shall assume an unwarranted attitude of dogmatism which may be evaluated at leisure

THE KINETIC MECHANISM

Man is a mechanism, an automaton, whose primary work is the transformation of energy by means of a system of organs especially adapted to this end In these organs during sleep is stored the energy which during consciousness, in response to environmental contacts with distance, contact or chemical ceptors, is transformed into muscular action, into heat or into the representations of muscular action, such as emotion or mental processes"

The impulse or driving force, which causes the transformation of energy within the organism, is supplied by certain parts of the brain, and in the brain is found also the mechanism which makes the final manifestations of the transformed energy specific to the environmental contact which initiated the driving

The initiators of the kinetic drive may be roughly classed as *contact ceptor stimuli* — physical injury, heat, cold, etc , *distance ceptor stimuli* — written and spoken language, sight, smell, etc , and *chemical ceptor stimuli*—infection, autointoxication, pregnancy, excessive food, poisons, etc Whether or not any one of these stimuli acts singly or in combination with others, the end-effects are identical The effects of any one, therefore, may be studied as typifying all the rest

The organs, which from moment to moment vary and control, accelerate or retard the driving force of the brain are the suprarenals, the pacemaker of the kinetic system is the thyroid, and the final act of adaptive energy transformation is performed by the muscles

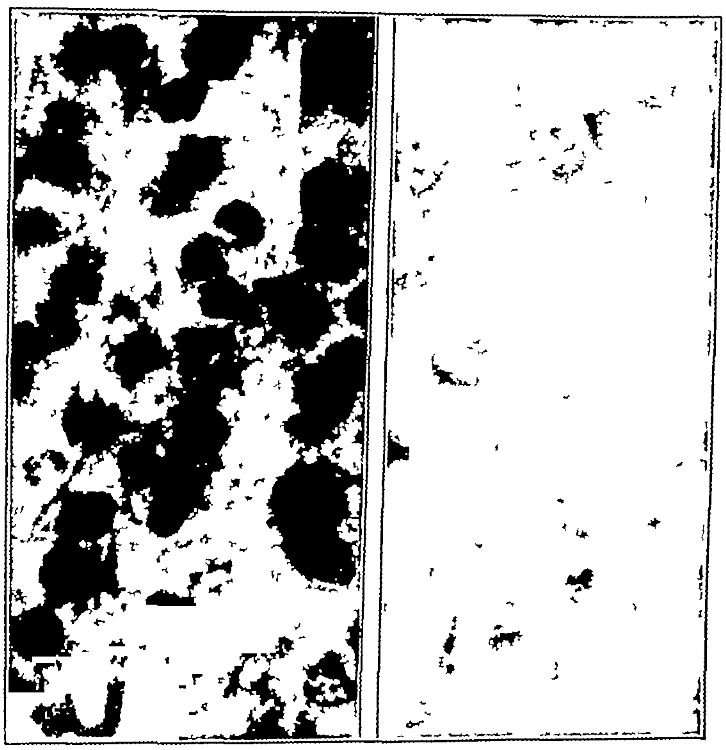
The primary process within the brain, by means of which its driving force is created and sustained, is oxidation Oxygen is supplied by the lungs If the blood be acid, oxygen cannot be carried by the hemoglobin Energy transformation depends, therefore, on the maintenance of the alkalinity of the blood Since the transformation of energy in the body is always accompanied by the formation of acid by-products, the continuance of the process of energy transformation demands a mechanism or mechanisms by means of which the acid by-products can be neutralized and eliminated These needs are met by the liver, the kidneys and the lungs The acid by-products of energy transformation are to a large extent broken down in the liver into simple compounds which are harmless to the kidneys by which these soluble end-products are eliminated, while the gaseous end-products are eliminated by the lungs

---

* Wesley M. Carpenter Lecture read before the New York Academy of Medicine, Oct. 7, 1915

If the system of organs, which we postulate is primarily adapted for the transformation of energy, acts as a *unit* and is restored only during sleep, then every excessive excitant of muscular action or of heat production between periods of sleep — such as prolonged consciousness (insomnia), muscular action, emotion, mental exertion, infection, foreign proteins, even pregnancy, etc, should cause identical changes in the histologic structure and the function of each organ concerned in the transformation of energy or in the neutralization and elimination of the resultant acid by-products, and in addition, intense and short, as well as long continued activation by any one of these agents should cause also identical acute and chronic diseases In other words, insomnia, intense *emotion* (*Figs* 1, 2 and 3), extreme exertion, infection, foreign proteins, pregnancy, etc, should cause histologic changes in the brain, the suprarenals and the liver, an increased output of adrenin, hyperplasia of the thyroid and a change in its iodin content, and changes in the glycogen content of the muscles and of the liver

If the foregoing be true, then it would follow that each of these activators would cause an increased production of acid by-products Therefore, exertion, infection, emotion, mental activity (increased consciousness) and foreign proteins or pregnancy should produce certain identical clinical phenomena First of all, we know that each of these activators causes increased respiration, increase in the frequency and force of the heart beat, thirst, excitability, perspiration, increased acidity of the urine, and identical manifestations of fatigue and exhaustion If the suprarenals determine the driving force of the brain from moment to moment, and if each activation of the *kinetic system* causes an increased output of adrenin, then it would follow that adrenin alone would produce the basic phenomena caused by an excitant of energy transformation — such as exertion, injury, infection, *emotion, pregnancy,* etc, and would produce identical histologic lesions, and it does In addition, adrenin given over a long period of time causes myocarditis, glucosuria, albuminuria, fatigue and in addition many symptoms of cardiovascular disease and of cardiorenal disease



A — Section of normal suprarenal of rabbit

B — Section of suprarenal of rabbit showing effect of extreme emotion (fright)

Fig 2 — Photomicrographs showing effect of fright on the suprarenals of a rabbit In *B* note the widespread loss of cytoplasm and the disappearance of nuclei

FUNCTION OF THE SUPRARENALS AND OF THE THYROID IN THE KINETIC DRIVE

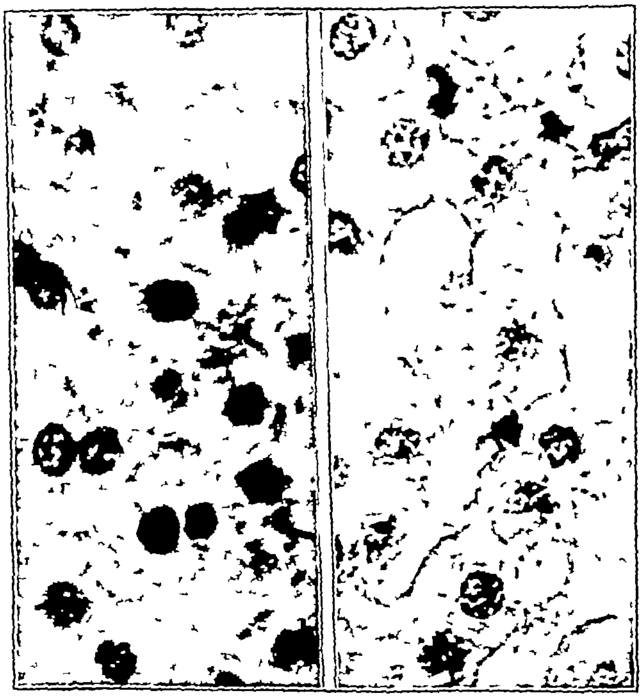
If adrenin causes phenomena identical with those produced by emotion, exertion, infection, etc, and if, vice versa, emotion, infection, exertion, etc, each causes an increased output of adrenin, then we may infer that it is through the increased mobilization of adrenin that increased energy transformation is accomplished by each of these activators Again, if this be the rôle of adrenin, we should find that in a state of suprarenal deficiency, the manifestation of energy transformation would be diminished And we find that this is true, for after double suprarenalectomy, there is an increasing and finally a total loss of muscular power and of heat production

If the nerve supply of the suprarenals is divided and then an adequate suprarenal stimulus applied, the output of adrenin is not increased If the nerves are intact and a large dose of morphin has been given, the application of an adequate suprarenal stimulus causes no increased output of adrenin (Figs 4 and 5)

We therefore conclude that the brain controls the transformation of energy by first driving the suprarenals, thus mobilizing adrenin, which is carried to the brain in the blood stream The result of the chemical combination of oxygen, adrenin and brain cell substance appears to be the production of energy impulses, these impulses being probably identical with electricity (Crehore and Williams) The electromotive force thus supposed to be fabricated in the brain is transmitted to the muscles, where the energy is finally transformed into heat, running, fighting, etc Since the suprarenals hold but a limited supply of adrenin, one would expect to find in the body some organ whose function is the secretion in abundant quantity of some substance by which the efficiency of adrenin is increased The belief that this function is performed by thyroid secretion is strengthened by the researches of Osterhaut, who found that iodin causes an increased permeability of living vegetable tissue to the passage of electricity The activity of thyroid secretion is directly proportional to the amount of iodin it contains, and we know that excessive doses of *iodin* alone cause all the phenomena of emotion and exertion, and, inversely, that emotion, infection, exertion, etc, cause changes in the iodin content of the thyroid If, in the midst of iodism, double suprarenalectomy be performed, the phenomena of iodism *should be diminished*

In this interrelation of the brain, the thyroid and the suprarenals, we have what perhaps is the master key to the automatic action of the body, that is, through the special senses environmental stimuli reach the brain and cause it to liberate energy, which in turn activates certain other organs and tissues, among which are the thyroid and suprarenals The increased output of thyreoiodin, by facilitating the transmission of electric currents through semipermeable membranes, increases the passage of nerve impulses and sets the pace for energy conversion In consequence the suprarenals are driven to increased activity, and the increased adrenin in turn excites the brain to still greater activity, the results of which are equivalent to increased work of the sympathetic nervous system These results are principally the following increased heart beat, increased respiration, raised blood pressure, increased sweating, thirst, the transfer of much of the blood from the splanchnic area to the surface, increased output of glycogen, increased power of the muscles to metabolize glycogen, increased acid excretion in the urine, certain histologic and chemical changes, and exhaustion

The phenomena of the kinetic drive in animals and in man are therefore essentially the phenomena of the kinetic drive of a locomotive The locomotive consumes carbon in the form of coal, man consumes carbon in the form of glycogen The locomotive produces heat and motion, man produces heat and motion The locomotive produces gaseous and solid acid by-products, so does man If the exchange of gases in the firebox of a locomotive is stopped, energy transformation ceases—the locomotive dies, if the exchange of gases in man is suspended, man ceases to transform energy—man dies



A.—Section of normal liver of rabbit.

B—Section of liver of rabbit showing effect of extreme emotion (fright)

Fig 3—Photomicrographs showing the effect of fright on the liver of a rabbit In *B* note the vacuolated spaces and other signs of disorganization

CONTROL OF THE KINETIC DRIVE

Turning from the phenomena of the kinetic drive to methods of control, we find first that morphin controls the rate of energy transformation in response to any stimulus Whatever the activation, whether infection, emotion, injury or exophthalmic goiter, morphin controls the outward phenomena, such as the pulse rate, respiratory exchange, sweating, thirst, restlessness, acid excretion, fever, muscular action and pain

The value of opium in infections and in pain is one of the foundation stones of medicine And here I must pause for a moment to pay tribute to a talented New York physician—Alonzo Clark—who on empiric grounds made a daring innovation in the opium treatment of peritonitis

Even today we must concede that next to surgical treatment the administration of opium is the most efficient treatment for peritonitis Guided by researches made in my laboratory, in collaboration with my associates, I have combined the administration of opium with surgical treatment in only those cases of peritonitis in which the kinetic drive threatened to kill the victim In such cases a quick *anociated* operation under nitrous oxid, Fowler's position, huge hot packs, saline infusions, sodium bicarbonate and glucose, plus the Alonzo Clark opium treatment for from twenty-four to forty-eight hours have given startlingly good results Opium blocks the kinetic drive, draining relieves tension, water and alkalies control acidosis, and the patient gets well Death from acute peritonitis from any cause has all but disappeared from the Lakeside Clinic The amount of opium must be determined not by quantity but by its effect on the drive, the respirations should be reduced to from 12 to 15 per minute In severe cases there must be no therapeutic faintheartedness

The final test of any theory in medicine is in the crucible of the clinic Our laboratory findings support not only the kinetic theory, but also the postulate that the kinetic drive may be controlled by the use of morphin, nitrous oxid and alkalies In the laboratory we have found that morphin prevents the mobilization of adrenin (Figs 4 and 5), that morphin and nitrous oxid block energy transformation, and prevent the histologic changes wrought by physical injury, infection and emotion (Figs 6, 7 and 8), and that alkalies counteract the effect of a kinetic drive by supplying the rapidly increasing deficiency of neutralizing bases These laboratory findings have been tested in Lakeside Hospital in a long series of operations on the stomach and the intestines, on the biliary tract, the pelvic organs and the appendix, in clean cases and in cases complicated by the severest acute infections, with a resultant remarkable reduction in both morbidity and mortality

The excessive energy transformation caused by physical injuries such as blows, crushes, penetrations, surgical operations, etc, like that caused by infection, may be blocked by morphin and nitrous oxid and the effect minimized by alkalies and water, and as in the infections, the dosage should be proportional to the intensity of the activation In surgical operations the brain may be insulated—and in consequence its driving power prevented by local anesthesia in the surgical field or by blocking the spinal cord or the nerve trunks communicating with the field While it is safe to block the kinetic drive by morphin in cases of acute injury or of acute infection, it is unsafe to use opium to block the effects of intense emotion, because of the danger of habit formation The tendency to habit formation, however, is the strongest possible evidence of the power of morphin to control the kinetic drive The emotional drive with its consequences, identical with the consequences of infection, exertion or physical injury, is best met through training and education leading to a philosophy of life that insulates the individual against destructive psychic stimuli Thus may the individual be anociated in the large clinic of life just as, through local anesthesia, the patient is anociated against the drive of the surgeon's knife

Never before has there been such an opportunity for studying the behavior of the human mechanism under the strongest physical and psychic stress as in warring Europe today There observations of the injured, of soldiers in the field, of prisoners and of refugees gave me an unparalleled opportunity for studying the human kinetic drive on a vast scale The illustrations show the gross effect of the combination of extreme emotion and exertion as they are manifested in the facies and bearing of Belgium refugees and of wounded soldiers, while the photomicrographs show the effect on the brain, the suprarenals and the liver of some of the kinetic stimuli to which these men had been subjected (Figs 9, 10, 11 and 12)

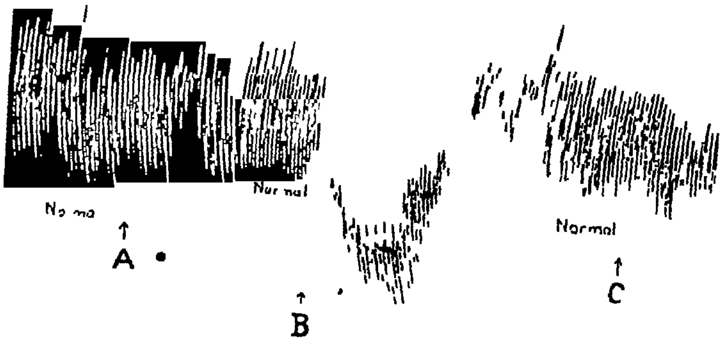


Fig 4—Tracing which, with Figure 5, illustrates the protective effect of morphin in anaphylactic shock (Cannon test) In this tracing it is shown that the adrenin which appears in the blood as a result of anaphylaxis inhibits the contractions of the intestinal muscle *A*, 5 c.c blood added from dog before anaphylactic dose was given, *B* 5 c c blood from dog in anaphylactic shock, *C*, 5 c c blood added from anaphylactic dog, after standing twenty five minutes

THE CHRONIC KINETIC DRIVE

Turning now from the individual acutely driven by injury, by infection, by emotion, let us consider the individually *chronically* driven by the stimuli of want, ambition, anger, jealousy or grief, by infection, by pain and by autointoxication In the acute kinetic drive the individual is endangered by death from exhaustion or from acid intoxication, whereas in the chronic drive, the danger is that one or another of the overdriven organs or tissues may be permanently injured In an acute drive, simple and direct control is possible, in a chronic drive we may encounter the added difficulties of pathologic changes in one or more organs or tissues I shall, therefore, discuss separately methods of control in those cases of chronic drive in which no organic change exists and in those in which organic changes do exist

The common chronic drives are mental and physical overwork, chronic infections, excessive diet and pregnancy, the emotions of fear, hate, jealousy, shame and despair, and foreign proteins, as in intestinal stasis These conditions present every-day problems and demand but little discussion Since the lesions of these various driving causes are the same, however, since infection, emotion and overwork produce identical end-effects, since usually two or more of these operate simultaneously, and since the emotional states are most amenable to control, it becomes obvious why these conditions have often been controlled by means which have apparently no direct therapeutic value, such as faith in the physician, travel, diversion, prayer, healing springs, philosophy and Christian Science Again and again, in the domain of regular medicine as in the domain of irregular medicine, the exclusion of worry has relieved the drive sufficiently to allow the body processes to overcome the primary disease But the reverse is true also — innumerable men, under the strain of a chronic drive, are pushed beyond the narrow limits of safety by the added drive of grief, worry or shame Is it not possible that when it is understood that the various kinetic stimuli have interchangeable physical values, the game of health will be more skilfully played? Incidentally, the chronic drive presumes a mild chronic acidosis — at least This, as Lawrence Henderson suggests, might be in part counteracted by alkalies and water

Passing now to that group of individuals whose organs have become affected by excessive energy transformation, we meet our greatest difficulties The proper prosecution of this theme would mean an extensive work on *medicine* I shall therefore give but a few illustrations

EXOPHTHALMIC GOITER

First of all, perhaps the most typical of the kinetic diseases is exophthalmic goiter In exophthalmic goiter the kinetic system is driven by a continuous activation, because in this disease there has been established a pathologic interaction between the brain and the thyroid, whereby the threshold to all stimuli is kept continuously low Exophthalmic goiter exhibits a progressive alteration in every function of the body, leading eventually to exhaustion, with visible lesions, depending on the duration and severity of the disease, in every organ and tissue of the body, not alone in the brain, suprarenals and liver, but also in the heart and blood vessels, the muscles, the thyroid, the thymus, the pancreas, the spleen, the lymphatics, the skin, the skeletal muscles, the teeth, the hair and the bony skeleton Extreme and protracted exhaustion from excessive exertion, excessive emotion or chronic infection causes similar lesions

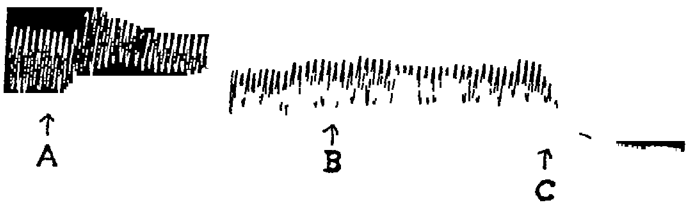

Fig 5—Tracing which, with Figure 4, illustrates the protective effect of morphin in anaphylactic shock (Cannon test) This tracing shows that the injection into a morphinized animal of beef serum, which in the normal animal would have caused a strong anaphylactic reaction and a greatly increased output of adrenin, causes no increased output of adrenin, as is evidenced by the contractions of intestinal muscle as in normal blood Since morphin acts directly on the brain, this experiment evidences not only the protective effect of morphin but also the dependence of the suprarenal on the brain for its activity *A* 5 c c control blood added from dog *B* 5 c c blood added from dog five minutes after intravenous injection of 15 c c beef serum *C* a few drops of pure adrenin added

In other words, the principal phenomena of exophthalmic goiter are identical with the leading phenomena of any other kinetic drive of a corresponding degree of intensity, and may be duplicated by fear, anger, sexual excitation, physical exertion, overwork or acute infection. Conversely, many of these activations cause hyperplasia of the thyroid. Thus fear, anger or sexual emotion may cause temporary enlargement of the thyroid, there is hyperplasia of the thyroid in pregnancy, in chronic infections, and perhaps in intestinal autointoxication as well.

There is a fundamental resemblance between certain aspects of exophthalmic goiter, of iodism, of suprarenalism, of emotion and of infection. The resemblance so often noted between exophthalmic goiter and excessive emotion is not surprising in view of the frequency with which the disease is traced to an emotional origin, for among the stimuli initiating exophthalmic goiter, protracted emotion is, perhaps, the most dominant. In a majority of cases, careful inquiry will disclose some deeply entrenched disturbing emotional factor — a great grief, the existence of harassing home conditions, poverty or shame, business reverses, overwhelming responsibilities, an unhappy love affair, or some acutely distressing thought, which drives the kinetic system incessantly. In my own experience, in cases of exophthalmic goiter, for the causation of which no factor in the external environment can be held responsible, the internal environment has usually supplied the disturbing factor, infection or autointoxication, for example. I have never known a case of exophthalmic goiter to result from hard physical labor, unattended by "psychic" strain, or from energy voluntarily and naturally expended.

Whatever the exciting cause of exophthalmic goiter, however, whether unusual business worry, disappointment in love, a tragedy, a strong fear, the illness of a loved one, intestinal autointoxication, an acute or chronic infection, or the administration of excessive doses of iodin or thyroid extract, the symptoms are identical and closely resemble the phenomena of one of the great primitive emotions.

INFECTION

There is a period of excessive kinetic drive in fever which exactly corresponds to the kinetic drive in emotion, and which signifies the preparation of the organism for self-defense by chemical activity, just as emotion signifies the preparation of the organism for self-defense by motor activity. The evolution of a receptor mechanism for foreign proteins may be explained on the ground that only by oxidation is the body able to split up and eliminate foreign proteins. The one method of inducing oxidation is through the kinetic system. The living protein molecules of the body are more resistant than the foreign protein molecules, and hence the body is purified by fire — by oxidation.

It would seem, therefore, that fever is the result of a driving of the kinetic mechanism by an infection (foreign protein) stimulus for purposes of self-defense by the splitting up of the molecules of the foreign protein through the transformation of latent energy into heat, and it would seem that emotion is the result of a driving of the same mechanism by a psychic stimulus for purposes of self-defense or procreation, in part at least, by muscular action, while exophthalmic goiter is a purposeless driving of the mechanism by some obscure disarrangement connected with a pathologic change in the function of the thyroid.

Reasoning from the secure facts of the clinic and the less secure data of the laboratory, I conclude that the primary lesion of exophthalmic goiter is the establishment of an abnormal facility for the passage of action currents in the central nervous system. As previously stated Osterhaut has given us definite data as to the effect of iodin on the electric permeability of skelp. There is evidence on a vast scale that such a state of increased electric permeability exists in exophthalmic goiter. It has been stated that electric currents are increased in the skin of patients with exophthalmic goiter. Exophthalmic patients are extremely sensitive to all stimuli: infection, autointoxication, injury, emotion and electricity.

Fig. 6.—Protective effect of morphin and of nitrous oxid on the brain cells of dogs which had received injections of diphtheria toxin. Compare the Purkinje cells in *C* and *D* with the disintegrated hypochromatic cells in *B*.

That these several activations involve the same mechanism is borne out by many points of similarity between exophthalmic goiter and infections The likeness of the phenomena of the kinetic drive in exophthalmic goiter to those of chronic infections, particularly of tuberculosis, is so marked that it is not at all uncommon to find diagnosticians of wide experience recommending treatment for tuberculosis to a patient with exophthalmic goiter, and an operation for exophthalmic goiter to a patient with tuberculosis In two different cases of the same degree of intensity, it may be almost impossible to distinguish the case of exophthalmic goiter from the case of tuberculosis Sometimes the two conditions may be present in the same patient The following symptoms are common to both exophthalmic goiter and tuberculosis tachycardia, increased respiration, flushed face, tremors, persistent slight fever, nervousness, rapid loss of weight, digestive disturbances, increased acid secretion of the urine, hyperplasia of the thyroid and of the lymph glands and enlargement of the heart Even at necropsy the lesions — barring the tuberculosis focus itself — may be so nearly identical in the two cases as to baffle differentiation In tuberculosis as in exophthalmic goiter, the entire kinetic system is overdriven

Thus the kinetic theory of exophthalmic goiter, of infections and of emotion supplies a possible biologic interpretation of the induction of these states, of their mutual resemblance, and of the method of their control All are modified by rest, all are temporarily controllable by morphin, all cause increased H-ion concentration in the blood, and, therefore, tax heavily the organs of acid neutralization, namely, the respiratory center, the kidneys, the suprarenals and the liver *The increased respiratory rate in each of these conditions is accounted for by the specific stimulative effect of the increased H-ion concentration of the blood on the respiratory center* The demand for neutralization of the increased acidity incident to emotion, work, infection or exophthalmic goiter is responded to by increased activity of the liver If the acidity is increased so rapidly that neutralization cannot keep pace with it, then nephritis may develop as an effect of the acid by-products on the kidneys Hence in intense emotion, exertion, infections and exophthalmic goiter, albumin and casts are frequently and sugar is sometimes found in the urine, and in extreme cases acute acidosis may develop The acidosis of emotion, of infection and of exophthalmic goiter is expressed in each case by thirst The cycles of vomiting in exophthalmic goiter are probably caused by acidosis, which is the most common cause of death in this disease Thus, in the immediate symptoms and in the end-effects, even to the resulting acidosis and pathologic lesions, we find a close resemblance in the essential phenomena of exertion, emotion, infection and exophthalmic goiter — phenomena which are harmonized and interpreted by the kinetic theory

CARDIOVASCULAR DISEASE

The analogy between diseases of the thyroid and diseases which among other organs involve the suprarenals is borne out by many clinical points For example, exophthalmic goiter and cardiovascular disease have many characteristics in common Each of these conditions bears an intimate relation to foreign protein activation and to "nervous strain" The etiology of exophthalmic goiter is much the same as that of cardiovascular disease In each of these diseases a recall of the unhappy circumstances or conditions which led to or precipitated the acute stage is sufficient to cause an exacerbation of all the symptoms The most efficient means by which each of these diseases may be modified are rest, diversion, and change of scene and occupation In each the secretion of the gland most involved seems to bear a specific relation to the production of the disease For instance, as has been stated, the cardinal symptoms of exophthalmic goiter may be produced in a normal person by the administration of thyroid extract, and in the patient with exophthalmic goiter the administration of thyroid extract, even in small quantities, causes an immediate exacerbation of the symptoms In like manner, adrenin aggravates the symptoms of cardiovascular disease, and when given to a normal animal in excessive dosage is said to produce lesions similar to arteriosclerosis Like results cannot be obtained by the administration of the secretion of any other gland in the body In exophthalmic goiter the thyroid is always enlarged, in cardiovascular disease, the suprarenals are usually enlarged

The literature of the etiology of arteriosclerosis is a long record of superlative stimulations and deep depressions, a story of great risks taken and great losses borne, of heavy burdens carried and long strains endured, of vast responsibilities assumed, of excessive dissipation, of chronic infection, of autointoxication of overindulgence in food and intoxicants, of great joys and great griefs, of hopes, anxieties and despair It is essentially a story of the modern world of power and progress and success, of liberty and luxury and of their antitheses, of mental tolerance combined with bitter, crushing oppression The contemplative scholar of the middle ages, the bucolic Swede, the wandering Scotch bard, the Italian peasant probably did not know arteriosclerosis, except as the logical accompaniment of a ripe old age The director of vast financial enterprises, the man who holds the fates of thousands in his hand, he who carries tremendous physical burdens, the Chinese coolie, the Japanese rickshaw man, the athlete of the western world, the emotional American, the excitable Jew, the bank president, the *bon vivant* — these are the men whose days are shortened by early hardening of the arteries, who preempt to themselves the cardiovascular, and likewise the cardiorenal diseases The superlatively emotional Jew, besides being a frequent victim of cardiovascular disease, is likewise a frequent sufferer from the allied condition, endarteritis obliterans Among animals, the high spirited wild animals in captivity, the mettled race horse and the dray horse, fretted and driven often beyond its capacity, are frequent sufferers from cardiovascular disease The somnolent, unfettered cow is exempt

BRIGHT'S DISEASE

In the great strain laid on the organs of reduction and elimination by the excessive acid by-products resulting from the kinetic drive of emotional activation, physical exertion and infection, we may find common causes of Bright's disease We have shown by experiment that in frightened rabbits, enraged cats and traumatized dogs the kinetic system can be driven at such a rate of speed that the organism is unequal to the task of neutralizing the too rapidly formed acid by-products so that they can be eliminated without injury to the kidneys In addition, we have shown that when the activity of the brain has been depressed by morphin, the rate of transformation of energy is decreased and the production of acid by-products correspondingly lessened If, as seems probable, the suprarenals and the liver are the most important agents by which the reduction of the acid by-products is accomplished, then a habitual failure of these organs to perform this function might lead to an accumulation of harmful compounds which would directly facilitate tissue degeneration in the kidneys, thus causing nephritis In Bright's disease, hyperplasia of the suprarenals is frequently seen

DIABETES

The more powerful excitants of the kinetic system cause an increased output of adrenin, and adrenin causes the mobilization of the glycogen stored in the liver so that, among other results of kinetic activation glucosuria is produced While glucosuria is not diabetes, it represents a step toward this disease, and one would expect, therefore, that the kinetic drive which in one individual causes the breakdown of the thyroid, in another of the brain, and in another of the suprarenals, in others might produce diabetes That this is so is shown by the fact that diabetes is improved by the conditions which obviate psychic strain The identification of the common causes of diabetes with the common causes of exophthalmic goiter, arteriosclerosis, neurasthenia and Bright's disease may explain why, in the words of a certain phrase maker, "when stocks go down in New York, diabetes goes up", why diabetes is more commonly found in large cities, among individuals and races who are constantly under a strain of business perplexities, and are constantly within sight and hearing of thousands of irritating and harassing episodes, and why it is rare in localities where leisurely and quiet ways of life prevail In the fact that here, again, the emotional trade-driven Jew is a frequent sufferer, we have important matters for consideration

Diabetes not only numbers among its common causes the common causes of other kinetic [illegible] ut also

as in the case of exophthalmic goiter, arteriosclerosis, neurasthenia, etc , it is improved by rest, diversion and dietetic control

SURGICAL METHODS OF CONTROLLING THE KINETIC DRIVE

It would seem to follow that a chronic disease which is made worse by increasing the kinetic drive would be improved by lessening the drive, and in like manner, would be improved temporarily by blocking the drive by means of morphin Morphin is but a temporary expedient, however, and the results of its use may be worse than the disease caused by the drive If the effects of morphin are produced by its control of the driving force of the brain, thus preventing the brain from driving the suprarenals and the thyroid, then a like result to that produced by morphin could be secured by breaking the connection between the brain and the thyroid and the suprarenals, by the excision of a portion of the thyroid and of the suprarenals, and, if still further blocking of brain impulses be required, by dividing the cervical sympathetics as well

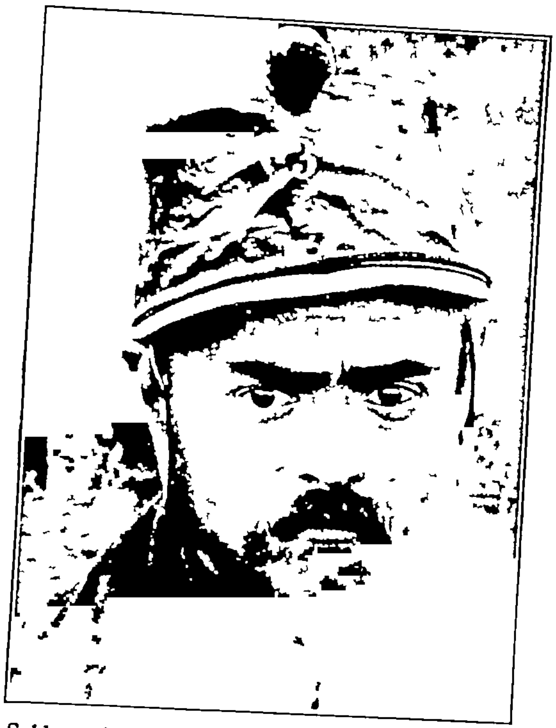

Fig 9 —Soldier showing the characteristic facies common to both psychic and physical stress.

One would not expect these procedures to produce any subjective change in the patient No function would be lost He could work, be subject to emotion, and respond to infection as before, with the following exceptions His power of physical exertion would be *diminished*, as would his response to emotional stimuli or to infection His acid excretion would diminish, and his sugar tolerance would increase In short, those diseases that are *temporarily* improved by morphin should be permanently improved by this process of *dekineticization*

On this conception I have ventured on new surgical ground and have performed fifteen operations on patients with chronic diseases resulting from an excessive kinetic drive I first operated on eleven hopeless epileptics, then on a patient with cardiovascular disease, on three patients with Raynaud's disease, and finally on an advanced diabetic All made good operative recoveries The operation, which was performed in different stages, comprised the excision of one suprarenal, the excision of approximately three fourths of the thyroid, and the division of the cervical sympathetics

It is now two and a half years since the first of these operations was performed It was not expected that epilepsy would be cured, but that the force of the attacks would be diminished, and perhaps the intervals lengthened, for since the epileptic attack represents a powerful temporary kinetic drive, it seemed possible that the severity of that drive might be modified No patient has been cured, but all made good operative recoveries, and the severity of the attacks and the length of the intervals have been favorably influenced The fact that some of these cases showed an increased sugar tolerance confirmed us in our belief that the same procedure might be of avail in cases of diabetes The principal net result of these operations on epileptic patients was the assurance that in man as in animals these procedures do not interfere with normal functions This fact being established, other fields are now being approached cautiously

In Raynaud's disease there is a striking diversion of blood to the extremities, in ebbs and flows These rhythms are in a measure determined by emotion, by cold, etc Since it is known that Raynaud's disease is most common in that emotional race, the Hebrew, that the most significant effect of emotion is the increased mobilization of adrenin, and that one of the results of the increased fabrication of adrenin is the transference of blood from the inner organs to the surface of the body, it would seem that this otherwise hopeless disease might with propriety be attacked on a kinetic basis Three patients thus treated by me, the first two and a half years ago, give fair promise

Fig 10—Effect of extreme activation on the brain cells of a soldier

of recovery But in a disease of such chronicity, the different phases of which are manifested in such long rhythms, judgment must be reserved until a long time has elapsed and until many cases have been observed

Since the kinetic drive may be concerned in greater or less degree in the causation or continuance of Raynaud's disease, exophthalmic goiter, Bright's disease cardiovascular disease and diabetes, on *a priori* grounds it is evident that either none or all of these will be benefited by a surgical reduction of the driving power of the kinetic system

Fig 11—Effect of extreme activation on the suprarenals of a soldier

I have already compared the effects of the kinetic drive on the normal human mechanism to the normal action of the locomotive In like manner the problem presented by these kinetic diseases may be compared to the effect on a damaged automobile of reckless driving by an irresponsible chauffeur In such a case the machine may be prematurely wrecked, whereas with careful driving at a moderate speed even the damaged automobile may give long service Vast numbers of men and women today possess such damaged mechanisms, which the stress of present-day life is driving to inevitable destruction Included in this doomed throng are many of the most useful men and women—the very kinetic temperament to which they owe their achievements proving to be also their greatest menace It is for such cases as these, in which medicine fails to provide the necessary kinetic control, that this surgical procedure is proposed In considering this operation, it must be borne in mind that we are dealing with poor surgical risks, and as far as the suprarenalectomy is concerned, a technically difficult operation Every possible protection, therefore, should be provided It is most important that the operation be performed under nitrous oxid-oxygen, rather than under the lipoid solvent, ether The principle of anociation should be applied throughout the operation, as the excessive acid-products resulting from cutting or handling sensitive tissues may diminish too much the narrow margin of safety and dispatch the patient Especially is this true of diabetes

The value of surgical modification of the kinetic system in that intense kinetic drive, exophthalmic goiter, is established We know that by dividing the nerve supply of the thyroid, ligating the thyroid arteries, or excising a portion of the thyroid gland, this disease is modified or cured In these cases the blood pressure falls, the myocarditis improves, albumin and casts disappear, the sugar tolerance is raised, the intense neurasthenia is improved In other words the renal, cardiovascular, glycogenetic and psychic phenomena simultaneously improve I have no doubt that in exophthalmic goiter the excision of a suprarenal, or the division of the nerve supply to the suprarenals, would also facilitate the cure

I have referred to the lessening of glucosuria by operation in certain cases of exophthalmic goiter It is well known that in cases of either suprarenal or thyroid deficiency, sugar tolerance is raised, while, on the contrary, the injection of excessive amounts of adrenin or of excessive thyroid extract mobilizes sugar Therefore, in intractable diabetes may it not be possible that the diminution of the total mass of the suprarenals and of the thyroid may sufficiently increase the sugar tolerance to mitigate or actually to cure the disease?

B—Section of liver of soldier described in Figure 10 The general disintegration of the cells the loss of cytoplasm and the vacuolated spaces within the cells illustrate the effect of emotion exhaustion lack of sleep pain infection and surgical trauma

Fig 12—Effects of extreme activation on the liver of a soldier

The patient with diabetes whom I have so treated through the courtesy of Dr C. F Hoover and Dr C. D Christie, Lakeside, is a *man* aged 42, who was admitted to L side Hospital in January, 1915 For a period mon June 25 when the first operation was the amount of sugar in the urine had ranged daily from 9.5 to 202.5 gm., with an average of 96.4 gm. At no time during these six months until the morning of the first operation was he known to be sugar free. In June at intervals of three and seventeen days respectively, the following operations were performed: (1) section of the right cervical sympathetic, (2) left suprarenalectomy, and (3) excision of the left cervical sympathetic with partial thyroidectomy. The patient made a good operative recovery. On the day of the first operation the sugar content of the urine was 83.6 gm.; on the following day it was 8.4 gm., since which time, with the exception of a few instances between the last two operations, he has been continuously sugar free. This patient now—four months after his first operation—is taking approximately 250 gm. of carbohydrates daily, and since his operation he has gained 9 pounds. It should be stated that Dr. Christie has continued a careful medical supervision of the case, employing the Allen treatment. Therefore, to obtain the surgical net result, we must subtract from this striking improvement the undetermined factor of the Allen treatment.

SUMMARY

The kinetic theory harmonizes many facts in the great clinic of life as well as in the restricted clinic of medicine; it emphasizes the value of a mechanistic view of life in the study of both normal and pathologic processes, and it suggests a philosophy of life by means of which self-preservation may be secured through kinetic control.

According to the kinetic theory, the resemblance of many normal and pathologic processes—exertion, emotion, infection, autointoxication, etc.—suggests that the mechanism by which they are produced is identical with the mechanism by which the transformation of energy and the elimination of acid by-products are accomplished; that is, that these conditions are caused by variations in the kinetic drive.

Since an excessive kinetic drive may be the result of the simultaneous action of various factors in the external and the internal environment, then the control of one or more of these factors will lessen the drive and mitigate its effect. Thus the substitution of hope for fear may relieve the organism of one driving factor and by so much relieve the strain on the kinetic system. In other cases the depression of the activity of the brain by morphin or by nitrous oxid anesthesia controls an acute kinetic drive.

For still other cases in which disease has resulted from the physical injury wrought in certain organs by an excessive drive, *it is proposed as a problem, not as an accomplished fact,* that the activating organs of the kinetic system, the suprarenals and the thyroid, be reduced in size and that their communication with the driving organ—the brain—be in part severed. By an analogous method the result of an intense kinetic drive—exophthalmic goiter—is modified or cured; the accompanying cardiovascular, cardiorenal, myocardial and neurasthenic symptoms are coincidentally relieved, and sugar tolerance is raised.

If exophthalmic goiter which is due directly to the overspeeding of the kinetic system is thus relieved by partial excision of one of the driving organs, the thyroid, this mechanistic treatment effecting simultaneously the cure of the condition brought about by the driving power of exophthalmic goiter itself, then the logical conclusion is that these allied diseases, when brought into existence by other kinetic drives, may be mitigated or cured by a dekineticizing operation. *A large amount of experimental data not yet published suggests this problem.*

THE TREATMENT OF PAROTID TUMORS BY RADIUM *

RICHARD WEIL, M.D.

NEW YORK

The second report of the Radium Institute of London describes a number of favorable results, characterized either as improvements or as cures, obtained in parotid tumors through the application of radium. The pathologic histology of these growths is not further specified in the text. The literature of the past few years contains occasional references to parotid tumors favorably influenced by means of radium; in no instance, however, so far as I am aware, had any of these tumors been submitted to a careful microscopic study. It is, however, unquestionably a matter of importance to determine whether or not any particular type of parotid tumors is especially suitable for radium treatment. Not all of the cases which have been so treated have been cured, and it would make for greater precision in treatment, if it were possible to determine that certain types of parotid tumors respond to the treatment whereas others do not. In the case which is here reported a small portion of the tumor was removed for diagnosis, and it is on that account that the case is reported in detail.

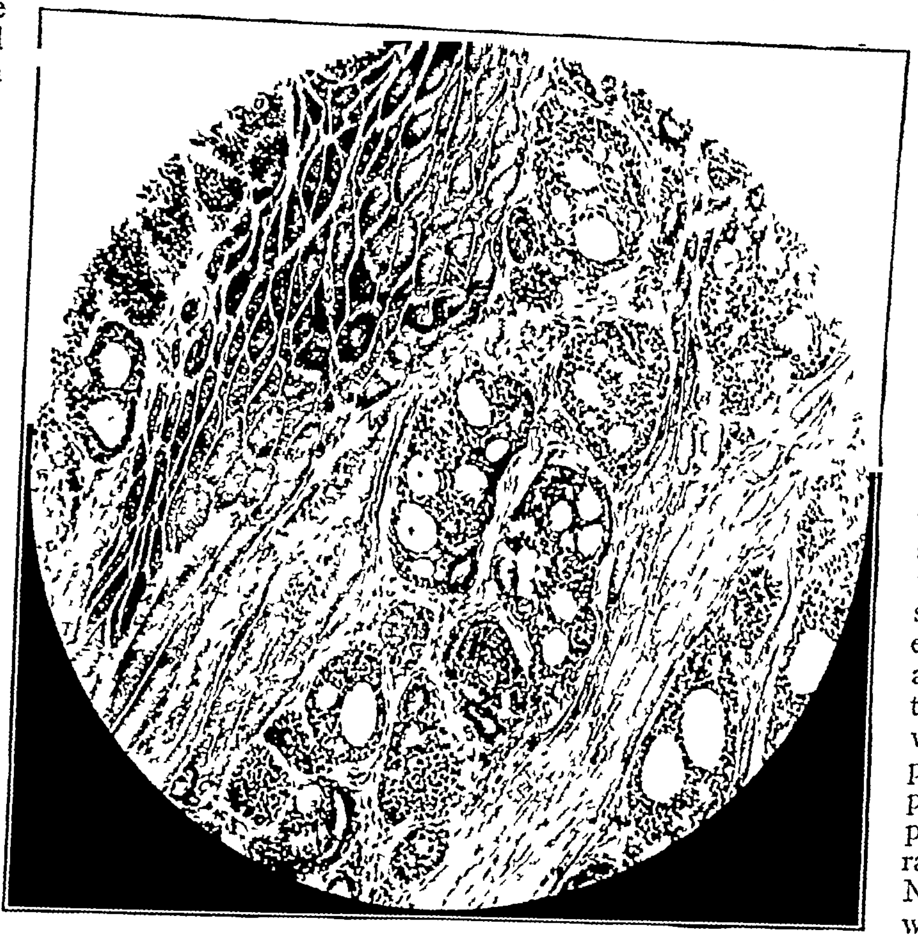

Fig. 1.—Photomicrograph of section of tumor.

---

* From the General Memorial Hospital.

The patient, an unmarried woman aged 38, was admitted to the General Memorial Hospital, Dec. 20, 1913. She gave the following history: Seven years previously she first became aware of pain located behind the right ear. Following this she observed an induration and swelling which first occupied the region in front of and below the ear. The swelling gradually increased in size, eventually involving the entire lower half of the ear and the upper part of the neck behind the ear. Difficulty in opening the mouth and pain during mastication induced her to have a number of teeth removed. In 1912 she developed the symptoms of facial paralysis on the right side. Toward the end of 1912 the right eyeball became somewhat more prominent.

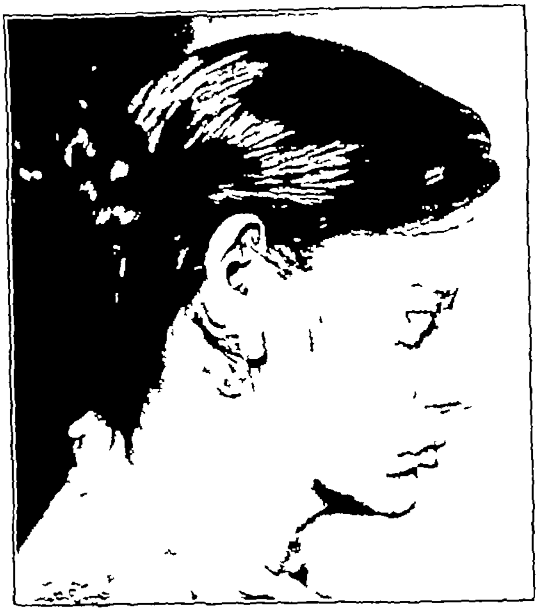

Fig. 2.—Appearance of patient, January, 1913.

The condition on admission was described as follows: The right ear appears very much deformed, the lower half being involved in an indurated mass which extends forward on to the face, and back of the ear over the mastoid process and the upper part of the neck. This mass measures from side to side 3½ inches, and from above downward 2½ inches. It is extremely firm and resistant to pressure, the surface slightly irregular and nodular. The margins are fairly well defined from the neighboring healthy tissues. The growth is firmly fixed to the deeper structures. The skin is movable over it except behind the ear, where it is firmly adherent. In the area where it is adherent the skin presents a reddish discoloration and has dilated superficial vessels. The lower half of the ear, which forms part of the mass described above, is distorted and densely infiltrated, and is firmly fixed to the remaining tumor mass.

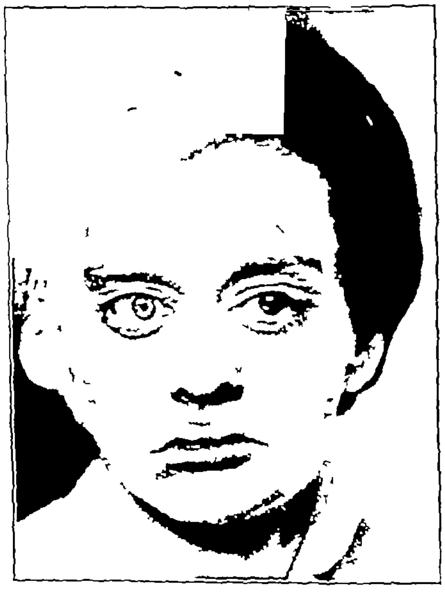

Fig. 3.—Appearance of patient, January, 1913.

There is a complete right-sided facial paralysis with right lagophthalmus.

Both eyeballs are more prominent than normal, but the right eyeball more so than the left. The pupils are equal, regular, and react normally. The right abducent nerve is paralyzed.

December 29, a small specimen of tissue was removed from that part of the tumor lying behind the ear. The microscopic section presents strands of epithelial-like cells in the midst of which lie hyaline masses. The appearance corresponds to that frequently described as cylindroma. On these sections Dr. Ewing rendered the diagnosis of "adenoid cystic epithelioma." A neighboring lymph node, which was removed with the tissue, had not been invaded by the tumor process. On the other hand, the sections show that the muscle bundles had been extensively infiltrated and were in large part destroyed. None of the types of tissue which ordinarily characterize the mixed tumors of the parotid could be discovered in the sections.

The classification of this tumor is of interest, inasmuch as it belongs to a type which has caused considerable discussion. Originally Billroth gave these tumors the name of cylindroma, for the reason that hyaline bodies of various shapes, but predominantly cylindric, could be expressed from them when fresh. As regards the histogenesis of cylindroma, there was considerable difference of opinion, some holding them to be sarcoma, some endothelioma, and still others carcinoma. It is now known that the hyaline character is one which may be shared by various types of tumor, and the name is therefore merely of descriptive, not of generic value. Discussion of this type of salivary gland tumor has in recent years centered chiefly around the question as to whether they are endothelial or epithelial in origin. Owing to the work of Hinsberg and many others, including latterly Marchand, the epithelial origin has now become well established. Krompecher accepted this view, but attempted to go a step further, and ranged these tumors with the basal-celled carcinomas, which have so charateristic a structure among skin tumors. It is true that in many respects they present a striking analogy with the basal-celled cancers. They are usually well encapsulated, nodular, slowly growing tumors, which may be surgically removed without likelihood of recurrence. Exceptionally, however, the epithelium shows an infiltrative tendency, and breaks through the capsule. Microscopically, also, the structure is similar in many respects to the basal-celled tumors. For these reasons it seems proper to consider these tumors as a separate group, differing in certain important features from adenocarcinoma as commonly understood. Although they resemble the basal-celled group in certain respects, it is not likely that they have the same cellular ancestry, for the reason that they have no connection with the epidermis. It seems correct to trace their origin to the salivary gland itself. Not improbably they arise, as Ribbert and others have held, from congenitally ectopic masses of glandular tissue, which assume an excessive, but not a malignant growth in later life. Thus it will be evident that the independent position of these tumors among the adenocarcinomas gives a rational ground to the expectation that they might react to therapeutic measures in a somewhat exceptional manner.

In January, 1914, a small incision was made into the tumor below and behind the ear in the most prominent part of the swelling Into this incision a trocar was driven to the depth of about 1 inch Into this cavity a tube containing radium was introduced In all, the patient received eighteen such applications The tube consisted of 10 mg of radium bromid shielded by 1 mm of lead It was left in position at each application for four hours The applications were made at first at intervals of three or four days, and subsequently at intervals of a week or more The applications caused no pain and very little local reaction Within two weeks after the beginning of the treatment the tumor began to undergo a marked change characterized by a diminution throughout its entire extent At the same time the induration gradually disappeared February 10, the patient was discharged At this time the tumor had almost entirely disappeared, and the parts had been restored to a condition approximately normal The lobe of the ear, however, still remained slightly swollen and indurated, a condition which has now completely disappeared The cheek, the neck and the mastoid region present no trace of their previous condition After her discharge from the hospital, the patient returned at intervals of about two to four weeks to receive Roentgen-ray or radium treatment At the present time there is no indication of any recurrence, although treatment has been suspended for many months The permanency of this recovery is, of course, not yet established

The facial palsy, which was unquestionably due to destruction of the facial nerve either by infiltration or by pressure, has not receded

A puzzling feature of this case is presented by the condition of the right eye Ophthalmologists to whom the patient has been referred have attributed the ocular condition to the presence of a retrobulbar mass pushing the eye forward and involving the sixth nerve Whether or not this mass can be brought into relation to the parotid tumor is a matter of speculation The ocular condition has not been affected by the treatment

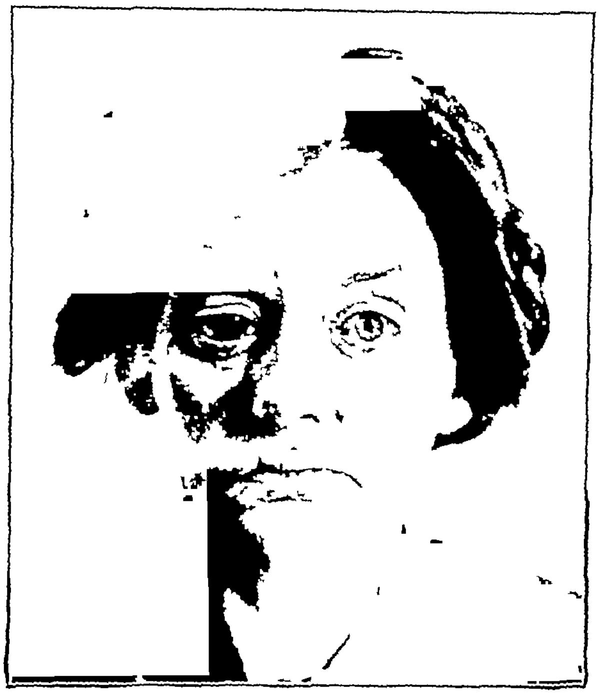

Fig 4 —Appearance of patient, July, 1915

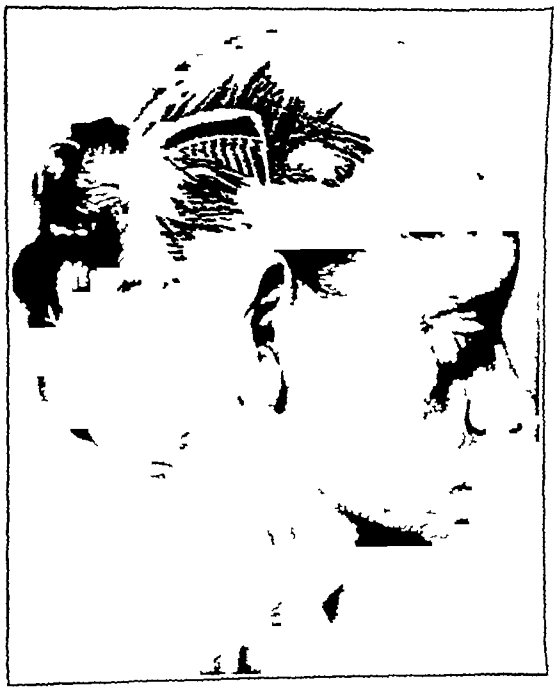

Fig 5 —Appearance of patient, July, 1915

SUMMARY

A parotid tumor of seven years' duration, presenting certain characteristic pathologic features, was treated for a period of six weeks by the insertion of radium into the tumor The tumor disappeared, and after an interval of almost two years presents no recurrence

TRICHINOSIS

REPORT OF A CASE WITH THE TRICHINA LARVAE IN THE SPINAL FLUID

LEON BLOCH, M D
Attending Physician, Cook County Hospital
CHICAGO

Early in 1914, Van Cott and Lintz[1] reported the finding of actively motile larvae in the spinal fluid of a patient with trichinosis Since that time their findings have not been confirmed until the finding of the larvae in the case herewith submitted

History—A K, man, aged 19, a laborer, entered my service in the medical ward of the Cook County Hospital, Oct 29, 1915, stating that he had had pains in the muscles of the arms and legs for four weeks, and that he was unable to straighten them out At the time of the onset of his sickness he noticed a slight edema of the eyelids which lasted three days Severe drenching sweats and periods of chilliness and fever had been present for one week On the night before entrance to the hospital he had a slight nosebleed He did not complain of any gastro-intestinal distress of any kind, nor had he had any headache Before entering the County Hospital he had been for three weeks in another institution where the diagnosis of trichinosis had been made from the history and muscular pain, but a piece of muscle tissue had not been excised for examination

The patient had eaten half a pound of raw hamburger steak every Saturday night for three weeks He did not smoke, was a moderate drinker and denied venereal disease

Examination—The patient appeared to be severely prostrated and was unable to move around in bed without considerable pain There was marked rigidity of the neck and tenderness of the intercostal muscles, the abdomen was diffusely tender to touch, both on superficial and deep pressure, the spleen was not enlarged There was marked tenderness of the biceps of the arms and of the calf muscles, while the other muscles appeared to be less tender, he was unable to extend the arm on account of the severe pain in the biceps The Kernig sign was present, there were no Babinski and no exaggeration of the patellar reflexes October 30, an excised piece of muscle from the biceps showed as many as ten unencapsulated trichinae in a low power field, many of which were also seen in the expressed muscle juice A blood examination at this time revealed 8 per cent eosinophils, 77 per cent polymorphonuclears and 15 per cent small and large mononuclears 13,000 leukocytes 4,200,000 reds and 83 per cent hemoglobin Two subse-

---

1 Van Cott, J M, and Lintz, William Trichinosis, The Jour A M A, Feb 28, 1914, p 680

quent examinations, November 23 and 24, showed 37 and 38 per cent eosinophils, respectively.

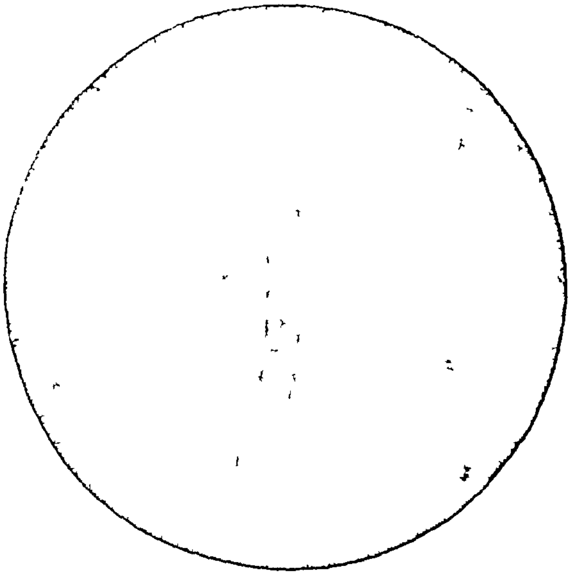
The patient's temperature on admittance was 101.2 F, and ranged from 99.6 to 101.4 during practically the whole time he was under observation, becoming normal about November 21. At that time he developed an acute tonsillitis with a temperature of 102 which lasted for three days and from which he recovered completely. A blood culture at that time was negative.

November 1, 20 c.c. of clear serous spinal fluid under high pressure were removed, positive to Nonne and Noguchi tests, and showing about a dozen actively motile trichina larvae in the centrifuged specimen. A puncture, November 8 yielded negative results aside from still positive Nonne and Noguchi tests; a cell count was not made at the time.

Treatment and Results.—Following the administration of calomel November 6, an enormous number of trichinae were found in the stool; these were found in small masses of mucus. The embryos were also found in the blood with the use of the Herrick and Janeway technic.

The patient now seems to have recovered completely, and is able to be up and about in the ward performing the duties of a ward man. There is practically no muscular tenderness.

The points of special interest in this case are the presence of the trichinae in the spinal fluid without symptoms referable to the brain or cord, the absence of gastro-intestinal symptoms, the small percentage of eosinophils at the height of the disease and their increase as the patient's condition improved.



Trichina larva from spinal fluid mounted on phenol gelatin.

Kafka[2] states that the cysticercus and trypanosomes have been found in the spinal fluid. On account of the absence of cerebrospinal symptoms in the majority of patients with trichinosis, the spinal fluid has not been examined for the parasite. The positive Nonne and Noguchi tests would indicate a meningeal irritation; this might be a clue as to the manner in which the parasites enter the spinal fluid.

In the consideration of the manner in which the parasites may enter the spinal fluid there are three possible sources of entrance: 1. Directly through the central capillaries of the choroidal villi. 2. Cushing[3] states that the perivascular lymphatics contribute to the cerebrospinal fluid, and it is possible that the organisms may gain entrance to the cerebrospinal fluid through this route. 3. Directly through the cerebral cortex into the subarachnoid space.

Sicard[4] cites a case of trichinosis which came to necropsy in the Boston City Hospital in which the trichinae were found in the cerebrum. It would seem probable, however, that the easiest mode of entrance would be through the choroid plexus.

The absence of gastro-intestinal symptoms has been noted on several occasions. McClure[5] in thirty cases reports diarrhea in nineteen, constipation in three, anorexia in fourteen. As the latter two symptoms have not provoked the distress that the diarrhea does, it can be seen that these symptoms may be easily overlooked. It has also been noted[6] that when rats are fed large quantities of trichina-infected meat, they die within one or two days without intestinal lesions.

The low eosinophil count during the height of the disease is not remarkable if we parallel this finding with the low leukocyte count in severe pneumonias, or the low resistance to infection when the body is overwhelmed by toxins. Gruber[7] found that very severe and unfavorable cases of trichinosis show a low eosinophil count. Van Cott and Lintz[1] cite an instance of 5 per cent eosinophils in a fatal case just before death. Herrick,[8] quoting Opie, makes a statement to the same effect. Only after the acute symptoms had subsided and recovery seemed certain did this patient's eosinophil count rise from 8 to 38 per cent. I have repeatedly seen patients with mild trichina infections at the Cook County Hospital with from 50 to 60 per cent eosinophils.

While several examinations of the stool failed to show the parasite, the administration of large doses of calomel caused them to appear in large, tangled masses, coincident with the appearance of the parasites in the stools the patient's condition began to improve.

CONCLUSIONS

1. Trichina larvae can be found in the cerebrospinal fluid.
2. Meningeal irritation undoubtedly exists, as is shown by the positive Nonne and Noguchi tests.
3. Severe infections show low eosinophil count during the acute stage, which increases with convalescence.
4. Vigorous catharsis with a view of clearing the intestinal tract from all parasites which have not yet penetrated into the mucosa appears to have limited the infection.

Comparative Vivisection.—The castration of an animal as performed on the farm by far exceeds in cruelty and callousness of performance anything which I have ever witnessed in a laboratory. A few hundred animals are used in all our laboratories for all purposes. The census report shows that in California, in 1909, there were born 163,728 bull calves. It is fair to assume that 150,000 were castrated. There were born 41,927 colts. Of these approximately one half were probably males, and making deductions for those kept as stallions there were here at the lowest estimate 19,000 geldings. There were 283,741 pigs born, which means probably 135,000 males to have their testes ripped out. A total each year in California of 304,000 operations. Comparing these in number and violence with the work in biological laboratories and medical schools, the latter becomes wholly insignificant. But the gelding of the boar does not have emotional appeal, and we hear little about it. Dehorning of cattle is painful but saves vastly more pain than they would inflict on one another.—S. S. Maxwell, *Science*.

SUMMARY OF CHEMOTHERAPEUTIC STUDIES IN EXPERIMENTAL TRYPANOSOMIASIS *

METHOD OF STUDY

1 *Therapeutic Experiments* —In our investigations, the following four parasites were employed the *Spirochaeta recurrentis* (the parasite of relapsing fever), the *Trypanosoma brucei* (the parasite of Nagana disease of horses), the *Trypanosoma lewisi* (a saphrophytic parasite in rats), and *Trypanosoma equiperdum* (the parasite of la dourine or horse syphilis)

Inasmuch as the influence of the drug administered on the duration of life of the infected animals was one of the important criteria of its efficiency, we found the *Trypanosoma lewisi* unsatisfactory because it does not as a rule kill the animal The spirochete of relapsing fever led to confusing results because of the frequent remissions and the disappearance of the parasite from the peripheral blood The *Trypanosoma brucei* killed rats within a few days, a period too short to study the effects of the weaker agents The *Trypanosoma equiperdum* was found admirably adapted to the purposes of our studies, and was the parasite generally employed by us It kills the rats in from five to seven days after injection

Fig 1 —Patient with hereditary syphilis

The series of rats were infected by intraperitoneal injection with *Trypanosoma equiperdum* according to the methods of Kolmer[1] By these methods, contamination is avoided and approximately known numbers of trypanosomes injected We have found this a matter of considerable importance, inasmuch as irregular methods of infecting the test animals, as by injecting enormous numbers of trypanosomes in one series and only a few in another, may readily influence the results, whereas with a uniform method, succeeding series of rats may be infected with approximately the same and known numbers of trypanosomes with uniform results capable of comparison

Rats were infected intraperitoneally twenty-four hours before the intravenous injection of the solution of the chemical under study With the numbers of trypanosomes injected by us (generally from 100,000 to 150,000 per rat) the parasites were practically never found in the peripheral blood until after the first twenty-four hours We have experimented with other methods consisting of the infection of the test animal followed immediately by the injection of the drug, and also by allowing forty-eight hours or more to elapse between infection and the administration of the drug, when the parasites had multiplied sufficiently to be found in the peripheral blood, but the foregoing method has yielded us the best results

Each animal was carefully weighed, and the quantity of the chemical injected was proportioned to the body weight It would be a serious error to inject a series of rats with increasing doses of the drug regardless of the weights of the animals, in all of our work, the chemicals were administered according to each hundred grams of body weight, and each dose was prepared separately in a sterile vial for each individual animal

The chemicals under study were administered dissolved in sterile distilled water so diluted that the dose was contained in exactly 1 cubic centimeter Intravenous injections were made into the jugular vein or in some instances into the caudal vein, the former method being preferred because it permits of absolute accuracy under conditions in which the loss of even a drop or two of the solution might seriously influence the results

Chemicals which were not soluble in water were employed in oil or incorporated in a fatty menstruum

and injected intramuscularly into the thighs Soluble drugs were also administered by mouth to rabbits and rats by means of a proper sized catheter used as a stomach tube

In every experiment at least four controls were included All animals were examined daily by securing a drop of blood from the tail on a microscopic slide, spreading with a glass cover and examining at once with 1/6 objective and a No 4 eyepiece (Leitz) The results were recorded according to the number of trypanosomes observed in a large number of fields, according to the scheme given under Table 1

There were necropsies after the deaths of the majority of the animals, and histologic examinations were made of the organs As pointed out in a former paper, even with the most careful attention to the weight of the animal, the dosage and the technic of infection and of administration of the drug, animals would not infrequently succumb for inexplicable reasons, likewise quantitative relations with minute and closely graduated doses of a chemical do not always yield uniform and graduated results It appears to be impossible to conduct biologic experiments of this character with justified expectation of precise mathematical results

2 *Toxicity Experiments*—The detailed results of an extensive series of experiments on the toxicity of the water soluble and insoluble salts of mercury will shortly appear in another communication[2]

In testing the toxicity of mercurial and arsenic salts, white rats and rabbits were employed Two methods of determining toxicity were employed by us, namely, the determination of (1) the immediate lethal dose (dosis lethalis) and (2) the largest dose that is tolerated over a prolonged but arbitrarily fixed period of time (dosis tolerata)

As in the therapeutic experiments, each drug was administered according to the weight of the animal, the dose for each animal being separately prepared in sterile vials with sterile solvents and diluents

In determining the immediate lethal dose of a chemical, rats and rabbits were injected intravenously and the immediate effects noted and recorded, for the tolerated dose, rats and rabbits were injected intravenously with water-soluble chemicals and intramuscularly with water soluble and insoluble substances

Rats were largely employed in the study of the toxicity of the mercurials, and both rats and rabbits for salvarsan and allied products

In determining the lethal dose of salvarsan and allied compounds in rabbits, the substances were prepared with sterile water as the solvent and diluent, and in such manner that 15 c c contained the entire dose per kilogram of body weight determined on The animal was then injected intravenously with 10 c c of the solution followed in a few minutes by the remaining 5 c c if no untoward effects were noted Each animal was then kept under close observation until death occurred, or for at least a month if it survived After necropsy, the internal organs were submitted to gross and histologic examinations In this manner we have made a great number of necropsies after the administration of various doses of salvarsan and allied products and at varying intervals after administration This material is being studied at present, and a full report will be made at a future time

The intravenous injection of a lethal dose of salvarsan into a rabbit is followed almost immediately by violent convulsions followed by a period of general paralysis Smaller doses may produce a brief convulsion followed by paralysis especially involving the hind legs, the animal recovering in from a few minutes to an hour

The injection of 15 c c of the fluid rapidly and without interruption is more likely to produce immediate effects than the injection of 10 c c followed in a few minutes by the balance of 5 c c The injection of 10 c c of sterile water or normal salt solution alone is without effect on a rabbit of average weight

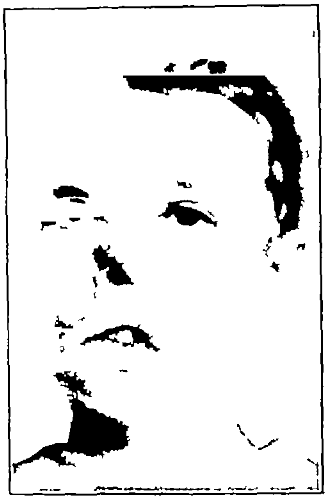

Fig 2—Patient in Figure 1 about two weeks later Patient received one dose of 0.2 gm of the salvarsan prepared in our laboratories no other treatment

INTERPRETATION OF FINDINGS, AND THEIR BEARING ON THE TREATMENT OF SYPHILIS

Of the various drugs employed by us, the only ones that were found capable of destroying the *Trypanosoma equiperdum* (and indeed, trypanosomes generally) in the blood of infected animals were those

belonging to the arsenobenzol group, namely, salvarsan and neosalvarsan

FAILURE OF MERCURY, COPPER, ENESOL, SODIUM CACODYLATE AND IODIN

Mercury, copper, enesol[3] and sodium cacodylate in the maximum nonlethal dosage exerted no appreciable effect on the number of trypanosomes in the blood, or on the duration of life of the experimental animal Scores of experiments were carried out with all of the well-known mercurial salts and with a number of new organic mercurial compounds made in our laboratory, but with the same results as were obtained with mercuric chlorid Iodin was likewise employed intravenously, but failed to exert any trypanocidal influence We recognize that the failure of these substances to influence trypanosomiasis does not indicate that they are equally inefficacious in syphilis Experimental trypanosomiasis is an overpowering infection in which the blood soon swarms with parasites which rapidly destroy life, unless a powerful trypanocidal drug is employed The trypanosomes react in large measure to the influence of drugs, as do the spirochetes, the spirochete of relapsing fever, which is resistant to the drugs mentioned above, is readily destroyed by salvarsan

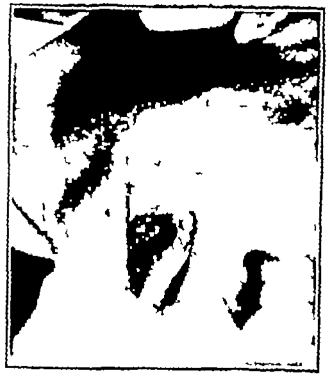

Fig 3 —Patient with chancre of the chin with accompanying adenopathy

We know, however, from clinical experience that mercury and the iodids exert a curative influence on the lesions of syphilis Whether they do so by the formation of some intermediate product which exerts a noxious influence on the spirochetes, or whether they stimulate the formation of antibodies, or whether they act in some other manner, is yet unknown

We are publishing elsewhere our studies of the toxicity of mercury, the effective dose of salvarsan is distinctly less poisonous than the effective dose of mercury This is due to the relatively low organotropism of salvarsan as compared with mercury By reason of this fact, salvarsan can be given in massive doses Experimental animals will stand 60 milligrams or more of salvarsan intravenously, per kilogram of body weight, whereas 3 mg per kilogram of mercury intravenously proves fatal

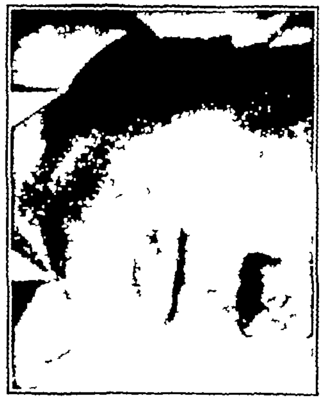

Fig 4 —Patient in Figure 3 two weeks later Patient received two injections of 0 3 and 0 6 gm, respectively, of the salvarsan prepared in our own laboratories

Our findings in animals convince us that weekly intramuscular injections of insoluble mercurials must of necessity lead to cumulative effect, with frequently severe damage to the kidneys We believe the safest effective way to employ mercury is by inunction

[3] Enesol An Arsenic and Mercury Preparation of Uncertain Composition, Propaganda, The Journal A M A, July 26 1913, p 293 Enesol has recently been shown to be a mixture of basic mercuric salicylate and methylarsenic acid

EXPERIMENTAL STUDY OF THE SALVARSAN PREPARED BY THE DERMATOLOGICAL RESEARCH LABORATORIES

The German product and the arsenobenzol prepared by us have been tested out on animals on a number of occasions The accompanying tables represent the average result It will be seen that the two preparations do not vary materially in their trypanocidal influence Both products, in adequate dosage, are capable of producing a permanent sterilizing effect When the dose is insufficient, trypanosomes may appear in the blood at the end of two or three weeks After they appear they invariably lead to the death of the animal We have found the sterilizing dose with the *Trypanosoma equiperdum* to be about 15 mg per kilogram of body weight Neosalvarsan has proved to be inferior in its effect to salvarsan This experimental finding harmonizes with the preponderance of clinical experience

Toxicity Tests—Our product has given most gratifying results as far as the immediate lethal intravenous dose is concerned[4] In the table setting forth these experiments it will be seen that 60 mg per kilogram of body weight is almost uniformly tolerated by rabbits, and at times they will stand considerably larger doses Unless this amount is well borne, we do not regard the drug as a proper one to employ, not that its use would jeopardize the life of a patient, but rather that it would be prone to produce more severe reactive symptoms The tolerated dose in rabbits is about seven to eight times greater per kilogram than the maximum dose that is given to man

TABLE 4—TOXICITY OF SALVARSAN (GERMAN AND DERMATOLOGICAL RESEARCH LABORATORY PRODUCTS) FOR RABBITS BY THE INTRAVENOUS INJECTION OF SINGLE LARGE DOSES

* This tube of salvarsan No A 25893 was purchased in the open market

CLINICAL RESULTS

We have administered our arsenobenzol intravenously over 175 times without any accidents whatsoever In a proportion of cases such reactive symptoms of chilliness, headache, slight fever, nausea and occasionally vomiting may occur, but these pass away in the course of a few hours The therapeutic results we believe to be indistinguishable from those obtained with the German product A healing influence on lesions is often evident in from twenty-four to forty-eight hours In the accompanying photographs are seen the effects of one and two doses of the drug, respectively

Several hundred doses have been administered by others than ourselves, and the reports we have received correspond with our own observations

---

[4] Rabbits that survive this dosage will as a rule live in apparent good health for a month at which time necropsies are made for histologic study

BERIBERI IN THE AMAZON BASIN

ALLEN M WALCOTT, MD
PORTO VELHO, RIO MADEIRA, AMAZONAS, BRAZIL

Beriberi is, as yet, a very common disease in the Brazilian portion of the Amazon Basin, and that means nearly the whole of the greatest river basin in the world The view of some foreign physicians in regard to this disease in Brazil is that perhaps beriberi here may be different from that met in other portions of the globe After having seen beriberi in San Francisco in 1906, however, and later treating and observing it in the hospitals on the Isthmus of Panama from 1907 to 1909, with a more recent experience in the employ of the Madeira-Mamore Railway Company during six years, from 1909 to the present time, in preliminary and location engineering parties, construction camps, operation camps and in the Candelaria Hospital, I am convinced that the beriberi of all these places is the same disease

The Madeira-Mamore Railway lies 1,500 miles from the mouth of the Amazon River, on the east bank of the Madeira River, in a dense tropical forest Malaria of a pernicious type, with its other form, blackwater fever, dysentery, pneumonia, ankylostomiasis, beriberi and leg ulcers are the commonest cause of patients entering the Madeira-Mamore Hospital at Candelaria, the only hospital for many hundred miles in any direction This institution is well screened and well equipped

An excellent article on beriberi conditions as seen here, by Dr Carl Lovelace,[1] former chief surgeon of the Madeira-Mamore Railway Company, is intended to show that beriberi in the Amazon Basin cannot have a food basis Under the prophylaxis and treatment as there laid down, seven doctors (one Scotchman and six Americans), some nurses and many laborers developed beriberi and were consequently either deported or buried Today, with few exceptions, the medical men of Brazil follow the same idea and have no faith in the teaching that beriberi is caused by a food deficiency

On coming to this country on vacation this September, I was much surprised to learn that many American physicians who have seen and treated beriberi in various parts of the world as well as in the Southern States still believe that this malady is propagated either by a micro-organism or is a place disease In recent conversations on this subject with some of these medical men, it appeared that there is much diversity of opinion and much faulty treatment

---

[1] Lovelace Carl The Etiology of Beriberi The Journal A M A, Dec 14 1912 p 2134

The object of the present paper is to demonstrate how readily beriberi may be cured as well as caused to disappear from any locality by the application of well-known dietary principles

At Candelaria, the Madeira-Mamore Railway Hospital had 30,430 admissions during the four years ending Jan 1, 1912, and in that number there were 963 cases diagnosed as beriberi Since then construction work has been superseded by operation, with a consequent decided lessening of the number of employees and a corresponding decrease in the number of hospital admissions, but cases of beriberi are always present in the wards

As I had long been a believer that a lack in the food was the causation of this disease, a decided change was immediately instituted in the food supplied at Candelaria Hospital when I became head of the medical department of the railroad, in November, 1912 It was impossible to enforce my views beyond the limit of the medical department Previous to November, 1912, the diet had been, for the first-class employees, on the line and in the hospital tinned vegetables in considerable variety, tinned baked beans (mentioned separately particularly), tinned soups, tinned meats, tinned fish, farina de agua, fresh Irish potatoes, dried Spanish onions, a few other fresh vegetables, some fresh fruit but more often the tinned variety, ices from tinned milk and cream, fresh milk (for patients only) and eggs daily, polished rice, and the following from white wheat flour macaroni, hot cakes, bread and pastries The food, especially at the hospital, was always abundant, of much variety and very tastily prepared

The laborers and second-class patients ate polished rice daily (when not replaced by macaroni made of white wheat flour), farina de agua, one and one-half medium sized loaves of white wheat flour bread (13 ounces actual weight), tinned codfish, tinned meats, fresh Irish potatoes almost always one time daily, and fresh meat or fresh fish once daily, while sacked dried beans were frequently prepared

When I took charge the following changes were made Polished rice, macaroni, tinned vegetables, tinned fruits, tinned soups, tinned fish and tinned meats were practically eliminated It was not possible to omit the white wheat flour, as the management would not consent to buy whole meal wheat flour or rye flour First-class patients and employees received at breakfast fresh fruit, cereal porridge, fresh eggs with ham or bacon, coffee or cocoa and toast, and at lunch and dinner two or three different fresh vegetables consisting of Irish potatoes, sweet potatoes, yams, pumpkins, squashes, string beans of many varieties, tomatoes, cabbages, kale, okra, yucca (or cassava or macaxeira), baked plantains, eggplant, corn, cucumbers, radishes and lettuce From dried peas and beans and lentils appetizing dishes appeared daily Soups of many varieties prepared freshly from beriberi-preventing articles were served at lunch and at dinner The fresh fruits on the table at breakfast and at lunch were from the following papayas (papaw of the West Indies), bananas of many varieties, watermelons, muskmelons, oranges, limes, mangoes, pineapples, water lemons, coconuts and alligator pears Very occasionally tinned fruits appeared There were fresh meat twice and usually fresh fish once daily For the patients the milk was almost all fresh, but tinned milk is yet used by the well employees A herd of cows is gradually being formed so that tinned milk is doomed

For the laborers and second-class patients the same eliminations in regard to rice, macaroni and tinned stuffs were observed and the following diet provided breakfast, half loaf of bread of white wheat flour, hot coffee, and as much as the man would care to eat of the following fresh cornmeal porridge, baked or boiled yucca, or baked plantains (cooking bananas) Lunch at 11 30 a m and dinner at 6 p m were prepared from the following always a tasty soup of beans, lentils, fish chowder, bouillon, or fresh vegetables, fresh meat once or twice a day, fresh fish once a day, half loaf of bread, and two vegetables from the following ordinary dried beans and peas comprising six different varieties, and the following fresh vegetables pumpkins, yucca, Irish potatoes, sweet potatoes, yams, plantains, beans, kale, eggplant and okra Fresh fruit daily or papayas, bananas, pineapples and oranges has lately been added

From these lists it is easily seen that previous to November, 1912, the first-class employees, if large bread and pastry eaters with a fondness for rice and macaroni, would easily overstep the danger line of lack of vitamins (neuritis or beriberi preventing principles) which are contained in the bran or inner skin of some grains, beans and peas, fresh vegetables, fresh fruits, fresh milk, eggs and fresh meat

The laborers with the diet that contained large amounts of white bread, polished rice, macaroni, farina de agua and tinned meats suffered considerably from beriberi, relatively much more so than the first-class employees

By the changes in the diet, effected since 1912, beriberi has been eradicated from the medical department of the Madeira-Mamore Railway, so that there has not been so much as one case among doctors, nurses or laborers during the past three years Absolutely the same surroundings have existed at the Candelaria Hospital for the first-class employees, laborers and patients during the past five years, every one always having plenty of fresh air in the quarters, living in screened houses and drinking the same water The kitchen, screened also, has had no renovation that has modified these conditions

Beriberi is much less prevalent among the other departments as the ideas of proper food value, demonstrated in Candelaria, are gradually being taken up outside the hospital In 1913, Mr Essaba lost 40 per cent of his laborers on his rubber plantation on the Jaci Parana River from beriberi, that is, many of them died, while those patients that did not succumb were invalided down the Madeira River The plantation lies two days by launch travel from the Madeira-Mamore Railway line where it crosses the Jaci Parana River Mr Essaba, hearing that there was something new in the prophylaxis and treatment of beriberi as practiced at Candelaria Hospital, consulted me He promised to carry out instructions, and within a few weeks' time beriberi disappeared from his plantation and has not reappeared The only change he made was in the diet as outlined above

Since 1912 the treatment at Candelaria Hospital for beriberi has been changed to a strict dietary condition consisting of

1 Soups of beans and peas, fresh vegetables, fish chowder and eggs

2 Meats all varieties, but served in underdone condition

3 Eggs, usually six daily
4 Fresh cow's milk several times daily
5 Irish potatoes, beans and peas and other fresh vegetables
6 Fresh fruits
7 Rice bran two times daily
8 No bread allowed as there is no whole wheat or graham or rye bread to be had here as yet

Strychnin, one-thirtieth grain, every six hours, by mouth or hypodermically always is given, digipuratum in ampules as indicated

Formerly, persons suffering from beriberi were immediately sent down the river to the sea as soon as possible, but now, unless there is marked paralysis (and the latter cases appear only among nonemployee patients who live remote from the Madeira-Mamore medical department), they remain at hospital from five days to four weeks and are then returned to work, having been very carefully instructed in regard to diet

By this changed system of treatment many thousands of dollars yearly are saved the various commercial communities in the avoidance of steamer passages invaliding the beriberi patients to salt water as formerly practiced, an increased security of life is felt by the employees so that they are now willing to remain a reasonable time at their contracted stations, a more normal wage has appeared in place of the very excessive former scale, a great decrease in the number of deaths has been secured and a much increased daily working power has been obtained

Patients who have been treated for beriberi at the hospital are returned to the same surroundings in which the disease was contracted, and as long as they follow the dietary instructions given them, never return again with this malady In 1909 the average stay of first-class employees on the Madeira-Mamore Railway was four months The mortality of this disease at this hospital is now almost nothing, whereas previously it had averaged about 15 per cent

Since 1912 the medical department has striven to have introduced for the consumption of our employees the unpolished rice for the polished, and wheat flour with the bran not removed, for the common white wheat flour, with also a plentiful supply of rye flour Shipments of all the foregoing have recently been ordered, and it is expected that within a few months' time beriberi, the disease most dreaded by the inhabitants of the Amazon Basin, will disappear from the list of the ailments suffered by the employees of the railroad

From observations made in Brazil, it would seem that beriberi must be more common in the United States of North America than the number of cases reported would indicate

EXPERIMENTS

Farina de agua, with the Brazilians of the Amazon Basin, is more esteemed than bread, and is partaken of in quantity, especially by the laboring classes, at all meals This product of the prolonged maceration of the wild or poisonous mandioca (*Manihot utilissima*), has been shown by the following experiments carried on by me for the past year with chickens to produce in fowls a condition clinically the same as avian polyneuritis or beriberi These experiments indicate a very important source of beriberi not usually met in other parts of the world, and never previously mentioned as an additional cause of this disease in Brazil Probably the fact that the Brazilians suffered from beriberi so much more, proportionately, than the other nationalities in this region was due to the consumption of this farina de agua in addition to their other faulty diet

Experiments with chickens were conducted at Candelaria Hospital during 1914 and 1915 as follows

June 7, 1914, four cocks and eight hens all apparently in good health, were divided into four lots of three birds each and placed in adjoining compartments, one cock and two hens in each division All compartments were about 8 feet wide, 10 feet long and 7 feet high, and were well ventilated and protected The chickens had plenty of fresh water at all times

Lot 1—Food Farina de agua solely, moistened and in *dry form* Fowls at first ate this food readily, but later with much less appetite

Cock died July 25 1914, emaciated, very weak and paralyzed

One hen died May 2, 1915, emaciated, very weak and paralyzed

One hen liberated July 16 1915, was weak and emaciated, but when last seen July 28, 1915, was regaining her strength

Lot 2—Same diet as Lot 1

Cock died emaciated and paralyzed, Sept 1 1914

One hen died April 2, 1915 emaciated and paralyzed

One hen died July 10 1915, emaciated and paralyzed

Lot 3—Food Farina de agua and Brazilian rice, each on alternate days This rice is polished, but not highly as is Carolina rice

Cock died Dec 27 1914 emaciated, weak and paralyzed

One hen died in condition similar to the cock, July 14, 1915

One hen alive but very weak and emaciated, liberated July 16, 1915 died July 19

Lot 4—Food Ordinary chicken food such as grass, kale, kitchen scraps, corn cooked beans, etc.

Cock and one hen remained perfectly well and in good weight throughout Liberated July 16, 1915

One hen died suddenly, Nov 11, 1914, was fat and strong till day of death Cause of death unknown

SUMMARY AND CONCLUSIONS

Beriberi in Brazil is the same as found elsewhere

Its cause is the same lack of vitamins in the food

Its eradication and cure consist in the furnishing of sufficient vitamins in the diet

---

THE TREATMENT OF PARESIS BY INJECTIONS OF NEOSALVARSAN INTO THE LATERAL VENTRICLE *

GRAEME M HAMMOND, M D
AND
NORMAN SHARPE, M D
Professor of Diseases of the Mind and Nervous System, and Neurologic Surgeon Respectively Post Graduate Medical School and Hospital
NEW YORK

Ever since the effect of salvarsan on syphilitic infection was satisfactorily demonstrated, it has been the hope of alienists that paresis, so long uninfluenced by any form of treatment, might be cured or at least ameliorated by this remedy To this effect many investigators have treated this affection by injections of salvarsanized serum into the spinal fluid and, more recently, into the cerebral fluid under the meninges Little if any benefit so far has been obtained in reducing the clinical symptoms of paresis by either of these methods It is true that the cell count has shown an appreciable diminution, and in some cases there has seemed to be some slight amelioration in the clinical symptoms, but so far nothing of any consequence has been accomplished

---

* Read before the American Neurological Association, May 7 1915

* Owing to lack of space this article is abbreviated in The Journal The complete article appears in the authors reprints. A copy of the latter will be sent by the authors on receipt of a stamped addressed envelope

It occurred to us that possibly the injection of salvarsan into the cerebral ventricle might accomplish more At any rate it could not accomplish less, provided the operation could be safely performed

In the first patient operated on, Jan 12, 1915, salvarsanized serum was used The symptoms of the disease were well marked Before the operation the spinal cell count was 75, and the ventricular fluid showed 220 cells The reaction was strongly positive The technic of the operation and of all subsequent operations will be described later in this paper The patient bore the operation well, there was no reaction, and he was able to leave his bed in two days January 26, the second operation was performed The spinal fluid and the ventricular fluid were both examined, and a remarkable reduction in the cell count was noted The spinal fluid showed 10 cells, the ventricular fluid 15 cells In this instance salvarsanized serum as prepared by Swift and Ellis, which was used in the first operation, was not employed Six-tenths mg of neosalvarsan was injected directly into the ventricle There were no disagreeable symptoms following this operation, and the patient was again enabled to leave his bed in forty-eight hours February 24, the third operation was performed on the same man, and was the exact counterpart of the second operation Before the operation the ventricular fluid showed 40 cells

Another patient who also showed well-developed symptoms of the disease was operated on March 18, and in this case the neosalvarsan in the same dose was injected directly into the lateral ventricle Further operations on this patient were prevented by the patient being seriously burned in a fire at his home, owing to which he had to be removed from our care and subsequently was taken into another state and we lost sight of him

Having established that the operation could be successfully accomplished, and believing that if any benefit was to be derived at all it could be only in the early stage of the disease, we selected such a subject and performed the first operation, March 12 His reactions were strongly positive The spinal and ventricular fluids both showed a count of 5 cells, the patient was able to leave his bed in twenty-four hours The second operation on this patient was performed March 31, and the third operation, April 21 Before the third operation the reaction of the cerebrospinal fluid was negative and of the blood doubtful

These seven operations are all that we have done, but the method employed by Dr Sharpe shows that it can be successfully accomplished without any danger to the patient at all Furthermore, it will be shown in the second part of this paper that the effect of the injection when made into the ventricle has a far wider distribution than when made into the spinal fluid

In regard to the effect of this method of treatment on the clinical symptoms of paresis, not much can be said at present However, the third case holds out some encouragement The man has been under close observation ever since, he has improved mentally and physically, and is able to do work he could not do before He has become more natural in manner, quieter, and more self-composed The emotional elements which were so characteristic before the operation have disappeared, and he is certainly better than he was when we first saw him

Of course it will take many more cases than these to determine whether this operation will accomplish more than is done by the subdural and the spinal methods We have certainly shown that the operation can be successfully performed, and we believe that further experience with selected early cases will show its decided superiority from a clinical standpoint

THE INTRAVENTRICULAR INJECTION OF SALVARSANIZED SERUM

This method, the intraventricular injection of salvarsanized serum, we have carried out on three patients on Dr Hammond's service at the Post-Graduate Hospital, the first injection being given Jan 12, 1915 We must confess that we were at first somewhat disturbed at placing a quantity of a possible irritating fluid so deep in the brain substance, but when we consider that the ventricles all the way to the fourth are lined with a layer of nonabsorbing cells, there is probably not much to fear from an injection which is not actively toxic The first patient received salvarsanized serum, three injections, the second, three injections of neosalvarsan, added to serum, according to Marinesco's method, but using only 0 6 mg neosalvarsan The third patient received one injection by Marinesco's method In the next patient we intend to use Ogilvie's serum While the first two patients have shown definite changes for the better, a statement of the progress at this early date would be valueless A most surprising thing has been the lack of reaction on pulse rate and temperature One patient had a temperature of 100 4 with headache for one day following two of the injections, with no change in pulse rate The others showed no reaction whatever

METHOD OF INJECTION

Under ether anesthesia, a small skin flap, slightly larger than the trephine used, is made a little in front of the bregma and 2 5 cm from the sagittal sinus A button of bone 1 5 cm in diameter is removed and the dura incised The slender cannula with blunt point is introduced at a point free from underlying cortical vessels and passed downward and a little backward into the lateral ventricle The head of the table is lowered, and from 10 to 20 c c of fluid allowed to escape The head of the table is now raised, and a funnel containing the serum is attached to the cannula by short rubber tubing The fluid enters entirely by gravity and is very slowly introduced The cannula is then withdrawn and the scalp wound sutured In the second and subsequent injections the scalp over the trephine opening is infiltrated with novocain, and the ventricular injection is carried out as described above As the brain is not sensitive, a general anesthetic is not required in second injections The fluid withdrawn from the ventricle at each injection is sent to the laboratory for complete examination

It was at first suggested that we introduce the serum by callosal puncture Foerster and also Ballance,[8] we believe, used this method But callosal puncture is more difficult to do, there is a chance, though slight, of wounding the sinus or one of the small pial veins which occasionally bridge over to the sinus from the inner margin of the hemisphere Further, on account of the higher pressure in the ventricles, the puncture in the callosum remains patent, and much of the serum would follow the cannula out of the ventricle when it is withdrawn The chief objection to the callosal puncture is that it is not applicable to injections under local anesthesia, the falx, in common with the rest of the dura, being exquisitely sensitive

---

[8] Ballance, C A Brit Med Jour, 1914 i 596

These considerations led us to adopt rather the penetration of the first or second frontal convolution which, so far as known, is a silent area

It may be urged that repeated punctures through brain substance may result in the formation of scar tissue and later trouble This may be true, yet in a hydrocephalic child on whom ten or twelve tappings of the ventricle had been done through the same area of the brain, at necropsy, macroscopic examination of the punctured area showed no formation of scar tissue, or even that an instrument had traversed it

COMPARISON OF METHODS

What are the disadvantages of the ventricular method in comparison with the intraspinal and subdural routes?

The intraspinal method is a much simpler procedure than either of the other methods, and requires no anesthetic But the serum is distantly placed and on experimental grounds but little of it reaches the cortex

The ventricular method may be considered a more formidable undertaking than the subdural, though in brain surgery, in skilled hands, ventricular puncture is a minor operation

What are the advantages, if any of the ventricular method over the intraspinal and subdural routes?

To determine, if possible, the relative amount of diffusion and rapidity of absorption by the subdural and intraventricular methods of injection, a series of experiments were carried out in the Department of Physiological Surgery of New York University and Bellevue Medical College

There were six series of experiments, one animal of each series having a solution of trypan blue introduced under the dura and the other into the lateral ventricle The quantity injected varied from 2 5 to 10 c c, and the animals were killed at periods of time varying from one hour to seventy-two hours following injection The two animals of each series received equal quantities of stain, and were killed at the same time The injections were made to conform in detail to the same procedure on man

Prof Douglas Symmers of the Department of Pathology of Bellevue Hospital Medical College examined the brains and the following is his report

> In the brains injected subdurally, the meninges of the injected side were deeply stained but the corresponding cortex was only slightly tinged and there was no penetration of the loose tissues lining the sulci The most deeply stained areas were at the base of the brain posteriorly the dye having evidently gravitated there in the subdural space before passing through the arachnoid to the subarachnoid space. The hemisphere opposite the site of the injection showed no effects of the stain, either in its meninges or elsewhere No stain was demonstrable in any of the ventricles The cervical cord and its *meninges* were deeply stained, the intensity diminishing as the cord proceeded downward On microscopic examination, the cells of the brain and cord were found to be unaffected by the dye
>
> In the brains injected intraventricularly, the stain was found to *be well distributed through the meninges and cortex* of both hemispheres, including the prolongations into the sulci, and extending forward to the tips of the frontal lobes and the olfactory bulbs The ventricles themselves, the cerebellum and the base of the brain were deeply stained In the spinal cord, the stain in the one-hour animals extended only to the midcervical region, but in the eighteen-hour animals, the stain not only penetrated to the cauda equina, but colored the tissues of the intervertebral foramina and the sheaths of the posterior root ganglia Microscopically, the *cells of the cord were unaffected by the dye*

These experiments demonstrate conclusively that solutions placed subdurally have difficulty in diffusing, and are rapidly drained out of the cranium

Apart from the subject we are discussing *these* experiments may supply the answer to the question of the direction of flow of the cerebrospinal fluid The dog injected intraventricularly with 8 c c of stain, and killed *in one hour, showed deep staining of both hemispheres* including tips of the frontal lobes and the olfactory bulbs, but the stain extended down the cord only to the midcervical region

Another dog, under the same conditions, and receiving the same quantity of stain, killed in one hour and twenty minutes, showed the same staining of the brain, but in the cord the stain extended to the upper dorsal region

A third animal with the same quantity of stain killed in two hours showed the same staining of the brain, and in the cord the stain extended to the lower dorsal region This was not due to lack of stain, for stain escaped when the meninges were opened at necropsy It was due to lack of time for the stain to spread, for in the fourth dog injected, under the same conditions, but with less stain, 6 c c, and killed in nineteen hours, the stain had spread over the brain entirely and over the cord throughout its entire length and along the roots of the cauda These experiments show, at least in dogs, that the direction of flow of cerebrospinal fluid is *from the ventricles up over the cortex* and then down over the cord

What are the advantages, then, of the intraventricular method?

Placing the serum in the lateral ventricles is placing it subarachnoidally at once, and also insures an even distribution over both hemispheres in juxtaposition to the cortical cells before it is drained out of the cranium Furthermore, the ventricular puncture obviates the lumbar puncture which is necessary in the subdural method, before the serum is introduced Again, the ventricular method brings the serum in contact with tissues that are not reached by the subdural route, namely, the ventricular system itself, and the base of the brain That it is necessary the serum should reach all accessible parts of the brain is shown by a case of Cushing and Sladen,[9] who reported the case of a child *with cerebrospinal* meningitis and subsequent hydrocephalus, in whom "after four months the diplococcus was found to be still living in the dilated ventricles, whereas the organisms had been killed off in the subarachnoid fluid" Also, *in our first* patient, lumbar puncture gave 75 cells per cubic millimeter, and the next day ventricular puncture yielded 220 cells per cubic millimeter This may or may not indicate involvement of the ventricles in the disease process

Finally, as shown by Mott,[10] the perivascular sheath spaces which extend between the neurons deeply into the brain substance, and drain it of waste products *communicate directly* with the subarachnoid space A serum, therefore, placed beneath the arachnoid membrane, comes into contact with the brain tissue, and this end is, we think, achieved best by the ventricular method

---

[9] Cushing H and Sladen F J Jour Exper Med 1908, x, 548

[10] Mott F W Lancet London 1910 ii 1 79

How many injections should be given?

We believe that in this we should be guided both by the serology and by the clinical symptoms But if the serology does not show steady progressive improvement under treatment, one should be guided rather by the clinical symptoms The number of injections naturally will vary with different patients and according to the extent and the severity of the disease process An unfavorable reaction to injection has been negative so far in our patients We intend to gradually increase the amount of salvarsan in the serum, and perhaps in this way reduce the number of injections necessary

CONCLUSIONS

1 In comparison with the deadly nature of paresis, the hazard of intradural treatment, by whatever method, is of little moment

2 On experimental and clinical grounds, both the subdural and intraventricular methods are superior to the intraspinal route, in the treatment of paresis

3 From an experimental and theoretical standpoint, the intraventricular method is superior to the subdural route, and we believe it to be safer

4 The intraventricular method, with careful technic, and a due regard for the anatomy of the brain and the delicate nature of the tissues one is invading, is, we believe, practically free from danger

5 If the freedom from unfavorable symptoms so far achieved in intraventricular injection can be maintained, it will be imperative to so treat paresis in its earliest stages, with greater chance of marked improvement and perhaps permanent arrest of symptoms

THE POSSIBILITY OF RECOVERY OF MOTOR FUNCTION IN LONG-STANDING HEMIPLEGIA

A PRELIMINARY REPORT

SHEPHERD IVORY FRANZ, Ph D, Hon M D, LL D
Scientific Director Government Hospital for the Insane
MILDRED E SCHEETZ, M S, M D
Assistant Physician
AND
ANITA A WILSON, A B, M D
Assistant Physician
WASHINGTON, D C

It is well known that in the hemiplegias due to cerebral lesions, there are usually early recoveries of function for different segments when the other acute symptoms of hemorrhage, or embolism, or trauma, subside The trunk muscles are affected the least in a hemiplegia, and there may be a complete return of voluntary control of them shortly after the cerebral accident The legs also frequently recover to a great extent, and although in many cases the distal segments may show evident signs of functional impairment, the larger muscles for the thigh and knee movements may be used with a surprising degree of ease and force Voluntary control of the arm movements is less likely to return, but if there is a return it is, as with the leg, better for the proximal than for the distal elements These recoveries ensue within a few weeks or months and are normal They result from the absorption of the clot, or the loss of the inhibition (or diaschisis to use the term employed by von Monakow) Subsequent improvements also take place, and at times a patient recovers his ability to perform a variety of movements in an apparently normal manner "After two years no further gain is to be expected"[1] After the early improvement which has been mentioned, "the case will be practically stationary,"[2] and the so-called residual paralyses are to be observed There are also secondary results The limb which at first was flaccid may become flexed (in the case of the arm) or overextended (as happens with the leg) In the arm segment, for example, the fingers are flexed the wrist is flexed and pronated, there is flexion at the elbow, and the arm is adducted at the shoulder joint These constant flexions result in contractures, with limitation of the possible passive movements at the joints, and the contractures are a deformity "The appearance of contractures implies lasting functional loss wherever they develop"[2] This is the usual statement of the course of cerebral hemiplegia

The results of experimental lesions in animals agree with the observations on man, with the exception that the paralyses are not permanent in such animals as dogs, cats and rabbits, and there is some doubt regarding the permanence of functional loss in monkeys and in the higher apes What difference exists between man and animals appears to be one of degree or completeness of functional loss and of time of motor recovery In animals the residual symptoms are more commonly those of asthenia, or of ataxia, or of paratonicity, rather than complete motor inabilities and contractures

A few casual observations made some years ago and results of animal experiments by one of us (F), together with experimental results of others, suggested the possibility that conclusions regarding the permanency of paralysis from cerebral accidents were neither accurate nor scientifically grounded, and that more attention should be paid to possible improvement in these cases In order that this view might be put to test, and that any results that might be obtained should not be open to criticism on the score that we were dealing with the normal early recoveries which can be expected in cerebral hemiplegics, the cases which were selected were old cases in which, in accordance with the dictum of neurologists, further improvement might not be expected All of the patients to a considerable extent, and some to an extreme extent, had developed contractures It was our object to determine, if possible, whether or not any improvement could be brought about, and if so to what extent All the cases were selected for us by other physicians, who were asked to send young persons, if possible, but no other limitation was placed on the choice except the ability of the patients to go to the laboratory for the tests During four months we have had opportunity to work with five patients, who had been committed to this institution and who exhibited different degrees of paralysis and also different mental abnormalities The arm segment being the most affected in all cases, was chosen for the treatments

Three general methods were employed The first was that of massage and vibration For the muscles which were strongly contracted effleurage, or stroking, was employed. The contracted muscles were stroked in order to reduce the hypertonicity, if possible. For the same reason the hand was grasped and the arm shaken or vibrated until there had been a distinct loosening of the muscles. The extensors were also percussed (tapotement) to give them the benefit of the mechanical stimulation, and the nerves of the arm were also stimulated by deep pressure.

---

[1] Church and Peterson Nervous and Mental Diseases, Ed 8 Philadelphia W B Saunders Company, 1914 p 223

[2] Church and Peterson Nervous and Mental Diseases, p 222

All kinds of movements of the arm were also produced passively when possible, special attention being given to extensions on account of the continued flexions. It was not found possible to pronate or supinate the arm in some cases at first, and the amount of passive extension was limited during the early treatments. In some cases much pain was experienced in these procedures.

The first two methods were employed in order to make possible the third, which was that of trying to get the patients to use voluntarily the extensor muscles in some simple activities. In some cases voluntary movements on the part of the patients could not be obtained for some weeks, but in all cases these were eventually obtained, as is indicated below.

HISTORIES AND RESULTS

Brief case histories of the patients with indications of the results of the treatments are as follows:

Case 1.—*History*.—Man aged 58, a former telegraph and telephone lineman, twenty years ago fell from a pole and fractured his skull in the left parietal region. This accident resulted in a right hemiplegia with an epilepsy. Four operations have been performed on him and a large piece of the skull has been taken away. After some of the operations he became more normal but was not entirely well. For the past seven years on account of his paralysis, etc., he has been unable to work, although for some time after his accident he was employed as a street sweeper. There are a spastic paralysis of the right side, contractions of the flexors of the forearm and hand, and adduction of the arm. The right ankle is almost immobile. The right side of the face is involved and saliva drools from the mouth. There is no apparent muscular atrophy. He is aphasic both motorially and sensorially, for he cannot name objects and his conversation is very limited and he does not appear to understand much that is said to him. The Wassermann reaction with the blood serum was negative. Mentally there is an almost complete amnesia. He replies to questions regarding his wife, children, business, home, etc., 'I forgot it,' but he has an oft-repeated series of sentences referring to his condition, which he uses as explanations of everything, and which he says whenever he does not apparently understand. Thus: "I feel all right. I can sleep, I can eat when I can get it, but it's the arm from here down." He complied with simply expressed requests but not with more complicated ones. It may be that the apparent sensory aphasia is only a kind of amnesia, the patient forgetting almost immediately what is said to him. After he had been in the laboratory about twenty times he was asked if he had ever been in it, and replied that he had not. He did not remember having had any exercises with his arm. This is a case in which the amount of cooperation was at a minimum, and whatever effects were produced could be referred to the daily work rather than to any efforts made by the patient independently.

Results.—At the time work with this patient began he could not make voluntary movements of his arm, hand or fingers. His arm was bathed daily with hot water an hour before he came to the laboratory. Massage and passive movements were used and the arm at the shoulder was forcibly abducted by means of a sling connected with a pulley at the ceiling. The first voluntary movement which we tried to get him to make, besides the gross arm movements, was that of opening his fingers after a ball was placed in his hand. The number of seconds which it took to loosen his fingers was noted. At first this movement was almost impossible for him, but after a comparatively few trials he was not only able to perform this movement but was also able to pick up the ball. The time of grasping and of letting go of the ball gradually decreased, although it was observed on more than one occasion when the number of these tests was large, thirty or more consecutive trials on one day, that the later trials took much longer than those at the beginning of the series. Not infrequently also it was observed that the lengthening of the time of grasping would be much prolonged, and there appeared to be a kind of spasm of the flexors. The quickest time for grasping and dropping the ball in ten trials was thirty-seven and a half seconds, but usually the ten trials ranged from sixty to about eighty seconds. The improvement in the ability of this patient to perform those movements on which he had been practiced was very noticeable not only with respect to the time of performance but also with respect to the accuracy of movement. No measure of the accuracy was made, and the conclusions regarding this factor are, therefore, due to the casual observations which we made and are qualitative.

Case 2.—*History*.—Woman aged 36, nine years ago during childbirth had an apoplexy, but subsequently bore two children at intervals of a year. She became aphasic at the time of the apoplexy but has regained some of her speech ability. There is a right-sided spastic paralysis, more marked in the arm than in the leg. At the time the present work began, the forearm was flexed on the upper arm, and the wrist and fingers were flexed with the exception of the forefinger, which was slightly extended. There have been convulsions dating from the apoplexy, although not at first numerous; they occurred as often as eighty-eight times in one month, but recently have been very few in number. The Wassermann reaction with the blood serum on three occasions has been negative, single positive and trace, respectively. The cerebrospinal fluid was negative; there were 2½ cells per cubic millimeter. Mentally, she was depressed when admitted to the hospital but has greatly improved, although depression is still present and prominent at times. She gets very angry at her inability to express herself and at her motor inabilities. She cooperated well in the work, doing all that was asked of her, although at times rather surlily.

Results.—When the tests were begun the patient could not raise the arm voluntarily in any direction without a considerable degree of flexion at the elbow, which with a maximum effort developed into a clonus. Rotation of forearm and extension of the wrist were impossible; wrist adduction and abduction very slight; dynamometric tests of the grip showed no power. Passive movements and the different forms of mechanical exercise of the muscles, especially of the extensors, were performed daily, and the patient was urged to perform similar simple movements voluntarily. The latter were done slowly, in a jerky, uncertain manner, and they often ended in a clonus. The trunk muscles were used to help out the movements of the arm in the performance of a given task and the larger arm muscles helped out the movements of the hand and fingers. During the efforts to move the paralyzed arm segments, the paralyzed leg frequently went into a clonic state. The ball test used with Case 1 was also used with this patient, and with results of considerable interest. At the time she was first able to grasp and to drop the ball she performed the movements in eighteen and nineteen seconds, respectively (average of three successful trials in ten trials). Subsequently after she had acquired the ability to extend the fingers better the fingers appeared to be flaccid and the time for grasping and for dropping the ball greatly increased at first (three to four minutes), but improvement took place gradually and at the present writing she averages four and twenty-five seconds, respectively, in the successful trials for grasping and for dropping, although at times she is able to drop the ball in two seconds. Grip is now slight but apparent with the dynamometer, averaging about 4 kilograms. The patient is able to use a pencil for drawing lines although not enough coördination is present to have them straight. The other movements are performed more steadily than at first, and with greater excursions, and they are not accompanied by clonic movements as in the beginning

Case 3—*History*—Man, aged 30, a former soldier, in 1909 when in the Philippines had a fever the nature of which is not known, and owing to this the patient says he became paralyzed and aphasic At that time the diagnosis of "gumma in the left cerebral hemisphere" was made, but the reason for this definite diagnosis is not clear At one time the Wassermann reaction with the blood serum was weak, and twice subsequently it was negative The patient exhibited a typical right-sided hemiplegia with aphasia, although he can to a certain extent make his wants known and can say a few words respecting common objects There was a hemiplegic gait, the foot was practically useless, the arm segment showed marked contractures Forcible passive extension at the elbow and wrist and movements at the shoulder could be made only with considerable "crackling" at the joints, and the patient complained of great pain when these movements were extreme The fingers and hand could be extended only by the application of great force The aphasia of this patient is largely motor, although he understands some things only after repeated explanations, and he cannot read Mentally, he is said to be demented, but the aphasic condition may account for this statement because it is difficult to determine how much he knows and how much interest he has in his surroundings He appears to be in the "moron" class although on account of the aphasia his mental status is difficult to determine At any rate, it is certain that his intelligence is slight and that he was poorly educated He is apparently very lazy and cooperates very slightly

Results—For three months this patient had passive movements and massage, but during that time he could not perform any except the grossest kind of movements of the arm He was unable to grasp objects and to make extensor movements of the hand and forearm, but at the present writing is gradually, but very slowly, obtaining some control both of the forearm movements and the finer movements of the hand and fingers By using the thumb and the ball of the hand he can hold a tennis ball, and by extension of the thumb he can release it He can also hold in a clumsy fashion a pencil, and can draw with it lines on a sheet of paper The lines are made mostly with the larger arm muscles At first the lines were not continuous, and were similar to the lines which a small child makes Now, the lines are continuous and are straighter They show great variations in force by the differences in darkness and breadth This patient was also practiced on the "piano" board, an apparatus made of contiguous squares which were to be pointed out consecutively by the forefinger, each square by a separate movement In this exercise the patient cannot use the extended forefinger, since he is unable to extend it sufficiently long for this purpose His hand is strapped to a board in a normal position, and a cardboard pointer is fastened to the board opposite the index finger At first he was able to make in five minutes sixty movements with his right hand when it was guided with the sound left hand, later, without the help of the left but with the cooperation of the trunk muscles, he was able to make 112 movements in five minutes, and at the present time, when the sound left hand and the trunk muscle assistance is taken away by strapping him into a chair and restraining these movements, he is able to make 120 movements with the right arm alone in five minutes No measurements of the amount of movement about the arm joints were made for three months on account of the apparent inability of the patient to perform the movements voluntarily At the time the first measurements were made, the movements were found to be slight, and after a month all had increased in extent. The following figures give the angular amounts of movement of different kinds, the first figure being the amount after three months' passive movement and massage, the second being the amount of movement after the succeeding one month's daily voluntary efforts Shoulder forward, 28 and 98, backward, 25 and 44 Elbow flexion, 94 and 107, rotation, 0 and 90 Wrist flexion, 4 and 33, abduction, 16 and 24, adduction, 23 and 41 Grip (by dynamometer) was 4 kg before and 6 8 kg after the month's work All these measurements are averages of five trials.

Case 4—*History*—Man, aged 36 had severe headaches in 1907, and later a convulsion with right facial and arm paralysis and aphasia Several months later there was added a paralysis of the leg At present there is almost complete right hemiplegia with aphasia The arm is flexed at the elbow and is spastic and slightly atrophied Little motion is possible A year after the paralysis of the leg an attempt was made to get the patient to use the leg with the aid of crutches, but this did not succeed, perhaps owing to the lack of cooperation The aphasia at the time of the present series of tests was practically complete He could copy some printed words, but could not say them He understood practically nothing, and could not repeat what he heard Mentally, he has varied, usually he is very emotional, and apparently very appreciative of the attention shown him, and he cooperates when he is made to understand by signs what is wanted of him On account of his lack of speech understanding, it was not possible to determine how much he understood of what was wanted, but his actions in an otherwise normal individual would indicate an overzealousness

Results—This patient was practiced on holding and dropping a tennis ball, and on the "piano" apparatus, as well as being treated with massage and passive exercises Not so much improvement was manifest in this patient as in the others with whom we have worked, but this may be due to the short time that work was in progress with him Some improvement was noticeable however in the time for the performance of the above-mentioned tasks Work with this patient was discontinued temporarily on account of lack of time, but it is expected that we shall begin again at a later date

Case 5—*History*—Woman, aged 58 The history of this case is very incomplete, for it is not known when the hemiplegia began It probably began several years ago, since she exhibited contractures It is stated that she had at different times, "fits," after which she could not properly speak When she entered the hospital she showed motor aphasia with apraxia[3] There were evidences of hemiplegia, her gait was a characteristic one, the right side of the face was paretic, and face movements could not be performed properly The leg could be used, but at the time of her entrance to the hospital she was not able to walk well without assistance The arm could be used for some of the gross movements, but there was a flexion at the elbow and wrist and fingers There was hypertonicity of the muscles and the reflexes on the right were exaggerated There was no atrophy The Wassermann reaction was negative Mentally, she has been depressed on account of her not being able to go home, but during the time of the present work she has been more cheerful She cooperated best of all the five patients, and was enthusiastic except at those times when the passive movements caused her pain

Results—We shall not repeat the data showing the improvement of this patient for the simpler methods of adduction abduction, pronation, etc, of the different arm segments, for they resemble greatly those of Case 3 The movements of this patient not only became more free but they were also executed with greater ease and rapidity than when the tests began After about eight weeks of the simple exercises, when she had learned to use the thumb and forefinger together, she was given a piece of muslin turned over for hemming and a needle and black thread to determine her ability to sew Her movements in doing this work were very awkward at first, as might have been expected, and they were slow At first also the movements were comparatively large, and this is shown by the fact that she averaged in the first week only 21.2 stitches in five minutes, and these extended over an average space of 122 mm This work was continued daily for five weeks and during the last week she averaged 33 5 stitches in five minutes, these stitches covering an average space of 78.5 mm. To practice the extension of the fingers and the combined coordinated movements of the arm and hand she was also given tennis balls to throw into a waste paper basket, which was set against the wall at a distance of about 6 feet from her. The first day she was able to throw into the basket only 2 balls of 25, but after four weeks averaged 15.8 out of 25. Shortly after she had learned to use the hand she was given a fan during the warm weather and she was urged to use it with her right hand. She grasped the fan properly, but could not make the necessary combinations of hand and arm in her first trials, but in a few days she succeeded so well that she was able to fan herself with the so called paralyzed arm and hand better than with the left arm and hand.

---

[3] A report of this aspect of the patient's condition has been made by A B Evarts Report of a Case of Aphasia and Apraxia, New York Med Jour 1914 c 1193

COMMENT

The results which we have obtained with these five patients show very clearly the possibility of a return of function in a paralyzed segment even after the paralysis has existed much beyond the time limit set by some neurologists for possible improvement. As far as the results from these cases go we have the right to say that the time limit beyond which improvement may not take place cannot be set. Furthermore, there appears at present no indication of a limitation of the quantity of improvement which may be attained by suitable and sufficiently prolonged therapeutic measures. It is also to be noted that these five cases differ with respect to the locations of the cerebral lesions (as far as these can be determined by clinical as contrasted with postmortem examination). One of the cases (Case 1) is doubtless a purely cortical case, another (Case 5) has been diagnosed as cortical, and the other three cases have signs which indicate more plainly capsular lesions. The examination of our records shows that improvement has taken place almost equally well whether the lesion be cortical or capsular.

The underlying causes of the cerebral lesions differ. Case 1 is definitely traumatic, Case 5 is probably arteriosclerotic, Case 4 is definitely syphilitic, Case 2 is probably syphilitic, and Case 3 is only possibly syphilitic. The most marked and quickest improvement took place in Case 5, and the least in Cases 1 and 4. We do not consider that these facts reveal any relation of special disease to the return of function, both because we have too few cases of any one kind for a definite conclusion and because we find great individual differences in cooperation of the patients, which latter fact appears to us to be more important. Since the diseased conditions which we mention, arteriosclerosis, syphilis and traumatism, are the most frequent causes of hemiplegias and other cerebral palsies, it would appear likely that most cases of cerebral paralysis can be treated so that improvement will take place.

Moreover, it should not be forgotten that the patients with whom we have dealt are patients who have been committed to an institution for the insane. They are, therefore, not mentally normal, and we could not expect and, in fact, we did not get the amount of cooperation from them which can rightly be expected from mentally normal patients. Our experience with the rapid improvement of Case 5 leads us to the belief that improvement may be rapid when the active cooperation of the patient can be obtained, but that without this cooperation, or with a minimum of it, improvement may be produced but slowly and to a slight degree. This is shown by the slowness of the patient in Case 3, who has been mentioned as lazy and noncooperative.

The facts which we have given briefly, and which we hope to add to and to publish in full at a later date, point to the conclusion that patients with any kind of cerebral paralysis should not be immediately consigned to the chronic, or incurable, or irrecoverable class, but should be intelligently dealt with just as any surgical case, and the effort should be made to relieve if not to cure. Every effort should be made to put into use with these patients all the means at our command to bring about a restoration of function or at least an amelioration of their helplessness. There appears to be no good reason why the discomfort and the deformity of contractures in cases such as we have worked with should be permitted to exist. Because of its popular pseudotherapeutic connotation we hesitate to use the term "mechanotherapy," but we would urge that properly used massage, passive movements, hot baths and packs, followed or accompanied by attempting to obtain on the part of the patient voluntary muscular contractions, be employed in all such cases. We recognize that treatment of the character mentioned cannot be given by any one, for, to speak only of massage, the ordinary slapping and rubbing which a patient may get at the hands of some well-meaning (but in this respect ignorant) relative or nurse may do more harm than good because the flexors may be stimulated much more than the extensors and the flexor condition be exaggerated. It is necessary to have some knowledge of the muscles involved, to limit treatments to those muscles which should be treated in this manner, and to see that the voluntary movements when they can be produced are directed to improvement in the movements which are in need of improvement. Elaborate apparatus is not needed, for much may be done with common objects which are to be found in any household. The principal requirement is a knowledge of the structures involved and their functional relations, with some ingenuity in the devising of means of bringing about movements of certain characters which should be practiced, and also different means which may help to stimulate the patient's interest and to show plainly to him the course of his improvement.

The facts are also of interest in a theoretical way in relation to our conception of motor cerebral control. If after the so-called motor cortex is destroyed, or the fibers in the internal capsule sectioned, by hemorrhage or by an anemia, there is a possibility of return of motor control, we shall have to modify our conceptions of how the different parts of the brain act in the production of movement. Experimental and clinical results are already at hand to indicate that there are great anatomic and functional differences in different brains and that the relations of the motor cortex to the limbs are not so simple as they have been supposed to be.[4] For recoveries of functions such as we have described there are many possible explanations. The simplest is that we deal not with motor inabilities but with exaggerated asthenias. This is an explanation of some of the motor deficiencies of animals from which the motor cortex has been excised. We should then look on the different forms of cerebral paralysis as exaggerated difficulties of movement and not as inabilities to move. We may also explain the recoveries as due to the assumption by another portion of the brain of the function of the motor cortex and the motor fibers. This was a favorite explanation of the motor recoveries of animals after ablation of the motor area on one side, it being assumed or concluded that the other hemisphere assumed the function of motor control on both sides of the body That this explanation will not hold, in animals at least, is shown by the fact that animals which have recovered motor power of the limbs after the removal of the motor cortex of one hemisphere do not lose this motor ability if the motor cortex of the other cerebral hemisphere be subsequently destroyed Another possibility is that the cerebral motor cortex may not be necessary for the production of movement but that this cortex is only regulatory It has been shown that if the motor cortex on one side be excised, a considerable number of the pyramidal fibers at the medulla on that side do not degenerate, and it would seem that, assuming the pyramidal fibers to be wholly motor in function, some of the motor impulses may arise in portions of the brain other than the precentral cortex The facts which we have already collected indicate that lesions of the motor cortex or of the upper part of the pyramidal tract in man do not abolish function, but put the function in abeyance until such time as the appropriate condition is present for the production of movement We should probably not speak of permanent paralyses, or of residual paralyses, but of uncared-for paralyses This we say because many of the conditions which we have met appear to resemble, if they are not real, phenomena of disuse, rather than actual inabilities

THE MANAGEMENT OF PNEUMOTHORAX OCCURRING AS A COMPLICATION OF NEPHRECTOMY *

WILLIAM C QUINBY, M D
Fellow of the American College of Surgeons
BALTIMORE

In cases demanding nephrectomy there not infrequently are found conditions external to the kidney itself which make an accidental opening of the pleural cavity very difficult to avoid Indeed, such injury to the diaphragm may occur in certain instances even under the most expert hand and with the most skilful dissection It may even occur during an operation of the so-called subcapsular type The cases in which this accident is most apt to arise are those in which the perirenal tissue has been greatly infiltrated with inflammatory products, thus fixing the kidney closely to its surroundings Dense adhesions to the diaphragm are more commonly found on the left side, owing to the fact that the kidney is normally higher on this side, and not in close relation to the liver During the removal of such a kidney, the procedure necessary for exposure may easily make an accidental rent in the diaphragm This most often occurs at the upper angle of the lumbar wound by traction either on the retractor or on the kidney mass, while an endeavor is being made to deliver the upper pole

Incision of the pleura may also happen in the presence of a rudimentary twelfth rib, in which case the operator may overlook this rib altogether, and call the eleventh the twelfth Such a mistake can be avoided by examining the ribs before operation, either on the patient or on the roentgenogram

While it is true that the pneumothorax caused in the manner referred to is usually small in amount and devoid of any special dangers except those of possible infection, this may not be so in each instance It seems also to be true that the genito-urinary surgeon is, in many instances, content to sew up the tear in the diaphragm as soon as it is discovered without any attempt closely to formulate to himself just what the possible contingencies of air in the chest may be, and what should be done to meet them

The severity of the functional disturbances following pneumothorax depends on the size of the opening in the parietal pleura If no adhesions are present, the lung collapses, but if the hole is smaller than the cross-section of the trachea, it will only collapse slowly, step by step, with each succeeding inspiration During the time required for this, it is very probable that the inadvertent rent in the diaphragm will have been recognized and closed But even though the lung be entirely collapsed, in a case in which the hole is smaller than that of the glottis or trachea, the pressure differences on either side of the mediastinum will not be so great as to cause any dangerous lowering of respiratory function in the great majority of cases Adequate ventilation will be maintained by an increase in the depth and frequency of respiration There will be no dyspnea or cyanosis, and no special burden thrown on the heart

It is in those instances in which the wound in the pleural sac is sufficiently large to allow free action of atmospheric pressure, that is, larger than the cross-section of the trachea, that phenomena follow dangerous to life In such instances the air enters rapidly, and in the side bearing the pneumothorax there results a continuous positive pressure This compels the mediastinum to bulge toward and from the well side with each succeeding respiration, and it is under such conditions that the active lung cannot expand enough to meet the demands of life The oxygen supply is diminished while the carbon dioxid is piled up, causing dyspnea and cyanosis of increasing severity

The latter condition is not very often caused by tears of the diaphragm such as are made in the manner referred to in this communication, though, to be sure, such tears, from the very manner of their occurrence, must always be of indeterminate length and size But whether the tear be large or small, it is my conviction that conditions within the thorax should be restored to the complete physiologic normal at as early a moment as is conveniently possible Should the lesion of the thorax be a large one and the patient show alarming signs of deficient ventilation, forceps such as are used for a sponge carrier, or ones with moderately blunt bite, should be pushed into the chest and made to grasp the collapsed lung By making steady, moderate traction on this, the mediastinum can be supported, and the uninvolved lung given a chance to carry on respiration till the tear can be sewn small enough to relieve the alarming symptoms The forceps are then removed, and the sewing finished

Similarly also, a small tear should be closed as soon as discovered If time permits, it is well to tack a bit of fat or muscle tissue over the line of suture, so as to make air-tight closure more speedy Closure of the diaphragm being ended, the operator may then proceed with the removal of the kidney, but before the final dressings are applied and the patient returned to bed, or even sooner if symptoms of insufficient ventilation persist, the air in the chest should be removed by aspiration This is best done by puncture low on the

side in the midaxillary line of the thorax. The trochar should be given a slant to correspond with the arching diaphragm, and suction should be made until, as read by a manometer attached to the aspirator, the chest shows a negative pressure of minus 7 to minus 10 millimeters of mercury. The latter procedure is important because it not only reexpands the lung to its normal position immediately, thus making atelectatic areas through collapse of the alveoli less likely, but also, if bacteria have entered the chest cavity at the time the pneumothorax occurred, these may become circumscribed in their action by the plastic apposition of visceral and parietal layers of pleura.[1]

REPORT OF A CASE OF ESOPHAGOTRACHEAL FISTULA

B. B. FINKELSTONE, M.D.
AND
T. LONG ELLIS, M.D.
BRIDGEPORT, CONN.

There are two forms of congenital occlusion of the esophagus, one in which the upper and lower parts of the occluded esophagus are united by a fibrous cord, and the other in which the lower portion opens into the trachea or one of the bronchi. The latter appears more usual (Osler).

St. Clair Thomson says that imperforation appears to be an arrest of development rather than a pathologic process in the fetus, while Losee explains the causes of esophagotracheal fistula, embryologically, by the fact that the proximal and distal portions of the esophagus have different sources of origin. The buccal cavity, pharynx and upper extremity of the esophagus develop from the ectoderm, and the intestinal tract, including the distal portion of the esophagus and respiratory apparatus, from the endoderm. Fistulous communications between esophagus and trachea are almost always situated at its bifurcation, and the conclusion may be drawn that the membrane separating the esophagus and trachea close last at this location.

According to statistics collected by McKenzie, sixty-two cases of esophagotracheal fistula have been reported in the literature. Since then Losee[2] has reported two in the new-born.

CASE REPORT

History.—A secundipara was delivered of a full-term female child by Dr. F. L. Day, labor was normal. Within a few hours, attention was attracted to the baby who became asphyxiated and was relieved by removal of large quantities of thick mucus from the mouth. The baby nursed well, but food regurgitated in a very short time as the infant would gag and choke and seem asphyxiated. Relief was obtained by passing a catheter, sometimes through the nasal orifices and sometimes through the mouth and removing the mucus. During the last days the mucus was blood-stained, owing, no doubt, to the passing of the catheter. Meconium was passed for the first three days, but there was no bowel movement on the fourth day and no report of stool on the fifth day. As no roentgenogram was taken, the diagnosis of stricture of the esophagus was made. (Ellis had seen a similar case last year of which no report was made.) The temperature on the fifth day was 102, when the child died of inanition and bronchopneumonia.

No operation was tried because gastrostomy seems to be of no avail, as milk introduced into the stomach is apt to be discharged into the trachea. Holt says, "Complete obstruction in the esophagus is almost of necessity fatal, the patient dying from inanition two or three days after birth." In the case reported by Losee, however, the patient lived for ten days.

Necropsy.—This revealed a full-term child, on appearance perfectly normal except that the nares were filled with clotted blood, owing no doubt, to the passing of the catheter. The abdominal cavity seemed normal. The intestines were inflated with gas. The stomach was tied off and cut at the pylorus. The esophagus was dissected as far as the trachea. The bronchi were cut at the bifurcation, and the trachea and esophagus removed *en masse.* The lungs showed minute hemorrhages on the surface. A catheter passed through the proximal end of the esophagus showed that it ended in a blind pouch at the fifth tracheal ring from the bifurcation. At the third ring from the bifurcation the distal end of the esophagus opened into the trachea causing a stricture at this site. Macroscopically there was apparently no continuity of the esophagus between the third and fifth rings, not even a fibrous cord. The remainder of the esophagus to the stomach seemed normal.

COMMENT

St. Clair Thomson says, "Congenital imperforation of the esophagus is generally regarded as a rare condition, but probably it is more frequent than has been thought, the comparative rarity causing it to be overlooked or symptoms attributed to some other cause."

Symptoms generally manifest themselves early. In this case attention was attracted to the infant in a few hours because of marked accumulation of mucus in the throat with gagging and asphyxiation. Vomiting is the chief symptom, and its occurrence should attract attention if the child is vigorous, if it sucks strongly and eagerly and if ingestion of food leads to coughing and choking.

Not being familiar enough with the minute anatomy of the new-born, we do not feel competent to say that the site of the various dilatations of the trachea change from birth to adult life. According to Braune and Stahel, the trachea is slightly expanded at the bifurcation, while in this case there was a stricture on the posterior wall, internally, below the esophagotracheal fistula. This stricture of the trachea was not due to pressure of the aortic arch, as the arch is normally situated a few tracheal rings above this site.

The probable explanation of this stricture is that there was an overgrowth of cells, either endodermal or ectodermal or a combination of the two, at the junction of the esophagotracheal fistula, causing stricture of the trachea.

Heat and Bacteria.—Many of the pathogenic organisms can grow only within a very narrow range of heat, and it is remarkable that their optimum temperature should correspond with that of the human blood. Considering their sensitiveness to temperature it is not surprising that microbes should be affected by climate and season and even by changes of weather. Most pathogenic organisms take on a more intense activity in hot countries and their virulence is no doubt affected by excess or deficiency of heat in the individual. It follows from these facts that if the temperature of the human body could be temporarily raised a few degrees the microbes of many parasitic diseases, if present in the body, would be destroyed and this is no doubt the intention and the effect of pyrexial reactions.—R. Fortescue Fox, *Clinical Journal,* Nov. 3, 1915.

THE DIFFERENTIAL DIAGNOSIS OF LESIONS OF THE LABYRINTH AND OF THE CEREBELLUM *

J GORDON WILSON, M A, M B
Professor of Otology, Northwestern University
CHICAGO
AND
F H. PIKE, Ph D
Assistant Professor of Physiology, Columbia University
NEW YORK

In this review we shall confine attention to three symptoms common to lesions in the labyrinth and in the cerebellum, namely, nystagmus, vertigo and ataxia We shall not attempt to discuss adequately these three symptoms in their various modifications by extension of the disease or its effects to surrounding structures, but shall chiefly consider lesions which are strictly and definitely labyrinthine and lesions which are strictly and definitely cerebellar We hope thus to be able to emphasize the points common to each and to note essential differences, if any, and thus arrive at the intelligent understanding essential to diagnosis

When one talks of a lesion definitely labyrinthine and definitely cerebellar one immediately thinks of experimental lesions As Dejerine[1] has pointed out, clinical lesions are not often confined, so far as their effects go, wholly to the cerebellum An abscess of the cerebellum is accompanied by the production of toxins which act, through the medium of the circulation, on neighboring or even on remote structures, a new growth in the cerebellum brings about changes in the general intracranial pressure, resulting in changes in the cerebral circulation, and, usually also, in an increased pressure of the cerebrospinal fluid[2] The increased pressure of the cerebrospinal fluid will in itself often lead to vertigo, quite apart from the destructive effect of the neoplasm, and the physical pressure of the tumor on the medulla oblongata and the floor of the midbrain may give rise to other phenomena not directly related to the structures involved in the lesion While the clinical picture may be necessary for diagnosis, the experimental picture must not be neglected in drawing conclusions with reference to normal function, and disturbance of function must be the basis for a rational diagnosis

While much of what is presented here is based on experimentation on animals done by us, it has received sufficient verification in man both in cases we have observed and cases recorded by others — often, as in the case of cerebellar nystagmus, without a full appreciation of the significance of what is recorded[3]

When we consider how close anatomically and physiologically the labyrinth is to the cerebellum, and when we recall that many of our labyrinthine cases when they come under observation have affected the posterior cranial fossa with more or less involvement of the cerebellum, and that so many cerebellar lesions are complicated by pressure on the vestibular nerve, it is little wonder that the most careful of observations leave us often hopelessly involved It is for this reason that we feel tempted to try to outline the essential differences of labyrinthine and of cerebellar lesions

It will be well here to attempt to define the physiologic function of the labyrinth and of the cerebellum This appears necessary because so much confusion has arisen concerning the primary disturbance and the remote effects associated with lesions in these organs

The primary function of the labyrinth is to give information of the change of position of the head in space[4] Its end-organ signals all movements of the head or, more correctly, all acceleration of movement Rapid changes of aspect of the head in space demand prompt and rapid motor reactions to preserve equilibrium or to break a fall A moment's thought will lead us to see the wide-reaching range of its reflex associations Thus it must be in touch with all the mechanism which tends to readjust the body and be able to call into play compensatory movements to maintain equilibrium There is no other sense organ in the body which will give this information quite so efficiently as the labyrinth, and hence, there is always a certain amount of permanent deficiency of motor response after total loss of the otic labyrinths

As a result of this we find (1) that the labyrinth is in such direct touch with the eyes that each movement of the head may have, when necessary, such compensatory movements of the eyes as are necessary to maintain the normal relation of the eyes to the horizontal[5] This, as we[6] have shown, is a direct reflex response independent of the cerebellum, with the probable object of insuring that retinal images shall not be disturbed by each movement of the head (2) We find that the labyrinth is intimately connected with the body musculature so as to prevent loss of balance When the usual limit of stimulation of the labyrinth is overstepped there are developed among other symptoms, nystagmus, and a fall to the side of the lesion, or to the side of the less intense stimulation

The fundamental action of the cerebellum is not so easily expressed nor are investigators agreed with regard to its full significance Sherrington would place it as the ganglion of the proprioceptors, that is, those end-organs or receptors which are buried in the body and adapted to react to stimuli developed in their neighborhood in the organism itself[7] It thus becomes a great coordinating center for the proprioceptors, and its destruction renders difficult or impossible the associating of movements directed to the same end

Babinski says that normally the cerebellum exercises a control action on voluntary movements Mills[8] expresses his conception thus "The fundamental symptom in cerebellar disease is asynergy" — defining synergy as "the power or faculty by which movements more or less complex, but functionally definite, are associated in a special act or acts" "Movements are mismeasured, giving dysmetry or hypermetry because the patient with cerebellar disease is unable motorially to associate the different elements of such movements" He quotes with approval Ferrier's idea of the cerebellar activity "Every form of active muscular exertion necessitates the simultaneous cooperation of an

immense assemblage of synergic movements throughout the body to secure steadiness and maintain general equilibrium" These ideas are fundamentally alike—so we will not be far from the current views when we say that the cerebellum is of importance to correlate such unconscious sensations from muscles and joints as assure the continuity and proper degree of motor activity in all our movements In our opinion, Luciani's objections to considering the cerebellum as the great central organ for the maintenance of equilibrium[9] have not been satisfactorily met

Mills classes as special symptomatic manifestations of asynergy, hypermetry adiadokocinesia and tremor As symptoms resulting from asynergic efforts asthenia (lack of motor power), atonia and ataxia Since the loss of strength is never complete, Sherrington[10] characterizes these conditions as parasthenia and paratonia

One sharp distinction between cerebellar function and labyrinthine function lies in the fact that the cerebellum is an afferent station for the proprioceptive impulses and the labyrinth is not Impulses simply originate in the labyrinth The cerebellum lies in one efferent path from the cerebrum to the cord, the labyrinth does not The labyrinth is a peripheral sense organ

LABYRINTHINE NYSTAGMUS

Nystagmus occurring as a result of a labyrinthine lesion consists of two phases, a slow lateral deviation, labyrinthine in origin, followed by a quick return movement, cerebral in origin This idea, expressed by us in former papers, has been confirmed by all our subsequent experiments, still unpublished On the basis of these experiments, we feel safe in saying that the impulses leading to the quick movement in labyrinthine nystagmus come from the cerebral hemisphere on the side to which the slow deviation of the eyes is directed The quick movement fails when the cerebral hemisphere to the side of the slow deviation of the eyes is extirpated These movements are synchronous in both eyes and vary definitely in direction with the labyrinth which is affected. In lesions produced experimentally or due to pathologic processes in the labyrinth, the movements are primarily horizontal, and it is the horizontal movement that is of importance The rotatory movement apparent at times, so far as our present knowledge goes, does not appear to have much diagnostic value, and insistence on it appears to us to confuse the issue When observed this rotatory movement is designated according to the direction of the quick movement at the upper end of the vertical iris meridian In nystagmus, after experimental lesions, the rotatory movements are of secondary importance and are most noticeable very early and again as the nystagmus is passing away

In experimental work the deviation is always to the side of the lesion We have never seen a case in which the deviation was to the side opposite the lesion so long as one labyrinth remained intact At first there is at times a slight vertical action, especially on the side of the lesion, the eye deviating slowly down, but even here it tends to the side of the lesion This stage, however, passes in a few hours As has been noted elsewhere,[11] in the very early stages the deviation can be made to go to the side opposite the lesion by mechanical pressure

An important question here arises as to whether we ever have a labyrinthine lesion with deviation away from the side of the lesion, that is, with the quick phase to the side of the lesion Theoretically, it is easy to reply that in the early stages of acute labyrinthine disease we have a serous effusion into the osseous labyrinth resulting in an irritation or stimulation within the semicircular canals which will produce such a deviation and nystagmus All the observations we have made leave no doubt in our minds that the normal stimulus for the end-organ is pressure But the pressure which arises in the course of a labyrinthine effusion is diffuse and different from the pressure arising from the definitely directed physiologic pressure of the fluids in the canals The pathologic effusion in such a small confined cavity rapidly becomes general if it be not so from the first, and results in a depression of activity We have no evidence that generalized pressure will act on the nerve terminals to cause an irritative lesion

In a serous labyrinthitis the effusion may be into the perilymph or the endolymph On general principles one would say that the evidence at present shows that in many cases the increase is in the perilymph, especially in cases which result in complete recovery In serous labyrinthitis the deviation is to the side of the lesion, the quick phase is to the sound side In the cases recorded with the slow deviation to the sound side during the course of an acute or chronic otitis media or following a mastoid operation but without the presence of a fistula, the opinion of Alexander[12] is that this indicates the period of irritation, presumably from serous effusion into the labyrinth It appears to us, however, that such cases are more correctly to be regarded as an irritation of an inflamed vestibular nerve, which inflammation may be outside the osseous labyrinth In the cases of nystagmus to the diseased side which we have observed occurring either during the course of an acute otitis media or after a mastoid operation, the deviation away from the side of the lesion had occasionally such additional symptoms (pain over the region of the fifth nerve, or paresis of the sixth or seventh) as pointed to some distinct involvement of the petrous temporal

There is an interesting table given by Ruttin[13] of the direction of the quick phase of nystagmus He there tabulates two varieties of labyrinthine lesions in which *on looking to the right or to the left* the general rule of slow deviation to the side of the lesion is not followed These are (1) circumscribed labyrinthitis in which the quick phase is directed to the diseased side or to the sound side or to either side—to the right on looking to the right, to the left on looking to the left, and (2) diffuse suppurative latent labyrinthitis in which also the quick phase is directed to either side on looking to that side

In circumscribed labyrinthitis the irregularity of the nystagmus is associated with a membranous labyrinth more or less intact but with a fistulous opening in the bone Ruttin[14] thus exemplifies it 'A patient with chronic middle-ear discharge has complained for some time of vertigo and perhaps also of tinnitus On examination there is more or less deficiency of hearing but not complete loss, the fistula test is positive, the caloric reaction is present, spontaneous nystagmus is present, and often toward both sides, that is, on moving eyes to right or left voluntarily" In the diffuse suppurative latent labyrinthitis we have a mechanical irritation of the nerve often associated with caries of the petrous temporal

[13] Ruttin Note 12 p 39

[14] Ruttin Note 12 p 35

The explanation in these chronic cases of this irregularity in the labyrinthine reaction on looking to the side is not very obvious, but we suggest that it is due to irritation of an inflamed vestibular nerve A suggestion of Luciani[15] is perhaps applicable here Claude Bernard, in his experiments on the nerves of recurrent sensibility, was unable to get his most pronounced sensory effects on stimulation of the peripheral portion of the ventral nerve roots immediately after the nerve roots were exposed in the spinal canal, the sensory effects were noticeable only when stimulation was made at least one hour after the nerve roots were exposed Bernard attributed this delay to the time required for the recovery of the nerve trunks from the shock resulting from division of the ventral roots Luciani is not inclined to credit this hypothesis of shock, but inclines to the belief that the nerve trunks become more sensitive to stimulation in the course of a few hours because of the development of the inflammatory reaction in the exposed nerve roots It is common knowledge that inflammatory processes in the joints or elsewhere often render the nerve endings of affected regions more sensitive to mechanical pressure, but it is equally well known that specialized nerve endings, for example, the olfactory endings, suffer early from inflammatory processes While it is possible that the vestibular nerve trunks might be rendered more susceptible to stimulation by the development of the inflammatory reaction along their course, inflammation within the ampullae would be more likely so to injure the cristae acusticae as to alter the normal threshold for pressure from the canals as a stimulating agent Under such conditions, it may be that head movements or increase of pressure in a localized area, which normally would not produce vestibular irritation, may become an efficient cause of vestibular irritation

We believe that the nystagmus in both directions, namely, in looking to the right the quick phase to the right, the slow to the left, and in looking to the left the quick phase to the left and the slow to the right, can be best explained by our hypothesis of two distinct sets of nerve fibers in the vestibular nerve for reasons already given This hypothesis, as we have already explained, is based essentially on Lee's findings that the differences in direction of movement of the eyes varies with the intensity of mechanical stimulation of the vestibular nerve endings, and our own observations on the results of stimulation when but one labyrinth is present

According to this hypothesis the vestibular nerve contains two groups of nerve fibers functionally distinct

(a) A numerous group of fibers excited by a strong stimulus turning the eyes to the opposite side

(b) A less numerous group of fibers more easily excited and hence affected by a weaker stimulus turning the eyes to the same side

In an inflammation of the left vestibular nerve both sets of fibers are affected and stimulated On looking to the left, a cerebral act, the left internal rectus and the right external rectus are relaxed so far as cerebral impulses are concerned The labyrinthine impulses are, however, still coming in to these muscles since there is no reason to suppose that cerebral action has any effect on the inflammation along the course of the vestibular nerve

Sherrington[16] has shown that electrical stimulation of the cortical area for movement of the eye muscles will, as an example, bring about contraction of the left external rectus and the relaxation of the left internal rectus, and that the mechanism for the inhibition of the antagonistic muscles is subcortical From this it will be seen that the suppression of the quick phase in labyrinthine nystagmus on voluntarily turning the eyes in the direction of the slow phase is associated with the relaxation of the opposing muscles whose tension we believe is the primary cause of the quick movement In any case of cortical relaxation or inhibition of a muscle, the relaxation is never complete, and the muscle is never slack A skeletal muscle always gapes when cut transversely In the lesions under consideration (say of the left labyrinth), in looking to the left the stimulus coming to these relaxed fibers from the stimulation of one set of fibers from the left labyrinth causes a contraction of these muscle fibers and a slow movement to the right Similarly, in looking to the right the left external rectus and right internal rectus are relaxed so far as cerebral impulses are concerned and the stimulus from the other set of left labyrinthine fibers causes a slow movement to the left There thus results a double nystagmus on directing the eyes to the right or the left

We have so far only considered pressure on the terminal organ in the labyrinth In lesions involving the vestibular nerve intracranially, causing pressure on or irritation of the nerve, there may be a deviation away from the side of the lesion Many of the so-called deviations of nystagmus are cerebellar or jointly cerebellar and labyrinthine and as such do not come within the scope of this paper

CEREBELLAR NYSTAGMUS

We have much to learn concerning cerebellar nystagmus For instance, we do not know sufficiently accurately the localities in which lesions may occur, yet be associated with no nystagmus, we have not sufficient data to differentiate between an irritative and a destructive lesion There are numerous experiments which show that cortical irritation of the cerebellum with the electrical current produces no effect so long as care is taken to limit the excitation to the cortex Luciani, Risien Russell and Horsley have shown that stimulation of the dentate nucleus produces deviation of the eyes to the side of the nucleus stimulated

The various articles descriptive of cerebellar nystagmus appear to us to be lacking in that clearness and definiteness which we are arriving at in labyrinthine nystagmus Here one is trammeled by observations made in cases which are not definitely cerebellar as well as by lack of appreciation of some of its characteristics We do not propose to present more than one quotation to exemplify this, and this we take from the school which has done much to advance the clinical applications of the physiologic facts although, it must be confessed, with some violence to these facts Neumann[17] in his work on cerebellar abscess says

[17] Neumann Otitic Cerebellar Abscess London, 1909 p 18

> The focal symptoms of disease of the cerebellum are due, on the one hand, to lesion of Deiter's nucleus and the afferent and efferent tracts, and on the other hand, to lesion of the secondary tracts, which belong to the same side of the body, and stand in relation to the co ordination of muscular sense The lesion of Deiter's nucleus produces vestibular nystagmus, vertigo, and vestibular ataxia As regards nystagmus, this is always of a rhythmical character, and shows on the whole the characteristic of a vestibular nystagmus, thus according with the description given by Barany The differentiation of vestibular nystagmus of cerebellar origin from that originating peripherally in the semicircular canals is made on the one hand by careful functional testing of the vestibular apparatus similar to that carried out by Barany in our clinic, whilst, on the other hand, the course of the disease and the accompanying symptoms assist in the diagnosis

If the description here given sums up the current opinion of cerebellar nystagmus we cannot agree with it Exception has to be taken to each paragraph If the first sentence means anything it means that cerebellar nystagmus is due to lesions of Deiter's nucleus and appears based on the erroneous idea that the labyrinthine nystagmus is dependent on an anatomic course through the cerebellum This we have shown is erroneous So far as the second is concerned of course a lesion of Deiter's nucleus will produce vestibular nystagmus because, as has been shown, it lies on the central path between the afferents from the ear and the efferents to the eye We do not believe that cerebellar nystagmus shows on the whole, the characteristics of labyrinthine nystagmus Unfortunately this teaching has formed the basis for most of our text book articles It lacks sound anatomic and physiologic basis and is not in keeping with experimental results More than that it is not in keeping with exact clinical observations

Experimental work early impressed on us that if there be one thing characteristic of cerebellar nystagmus it is that it is not comparable to labyrinthine nystagmus It differs from it (a) in uniformity of direction, and (b) in character

Some years ago we stated that cerebellar nystagmus was essentially ataxic and we have seen no reason to alter that opinion Its distinctive feature is its character — its oscillatory nature approaching toward an ataxia of the eye muscles With the animal at rest it is lessened or may disappear It is increased by fixation — especially at the beginning and during the intensity of the fixation In other words, it is to be regarded as an asynergia Behind glasses, when the patient ceases to focus, it tends to become less marked, and here again differs from labyrinthine This is in keeping with what has been said above in regard to the known function of the cerebellum A lesion here will produce an incoordination of movement, and movements of the eye muscles offer no exception

In direction the slow deviation may be away from the side of the lesion though it may be to the sound side, depending on whether we are dealing with an irritative or destructive lesion But it tends to be irregular in the plane of its direction with the head at rest

VERTIGO

Vertigo, as we have stated elsewhere,[18] is the confusion resulting from the coming into consciousness of afferent impulses concerned with orientation in space which ordinarily are associated (integrated) but now for some reason have become dissociated We will not concern ourselves here with the variety of sensations which are embraced under the term vertigo, the majority of which are too indefinite to be of value in diagnosis We will only refer to vertigo associated with the sensation of rotation It is well to emphasize that in vertigo we are dealing with a subjective sensation and as has been said elsewhere[19] "One notes how difficult it is to get a distinct history of subjective sensations even from intelligent patients, and further, how much less reliable are the subjective sensations of apparent movement of external objects"

The law applicable to apparent rotation following stimulation or destruction of the labyrinth is that apparent rotation of oneself is always in the direction of the rapid phase of nystagmus There is not the same unanimity in regard to the apparent rotation of objects "In postrotary visual dizziness Barany sees the visual field oscillate from side to side in both directions, whereas Mach, Breuer, Delage and most other observers see it whirl contrariwise to the preceding actual rotation and Helmholtz saw it whirl sometimes with and sometimes contrary to, the direction of the preceding rotation"[20] Our observations confirm the findings of Holt that as a rule the postrotatory apparent rotation of objects is contrariwise to the preceding actual rotation, that is, in the direction of the quick phase of nystagmus If no nystagmus be present the apparent rotation of self points to the side of the lesion[18]

Less uniformity exists in cerebellar cases On this point careful observations were made in a series of forty cases of tumors involving the cerebellum by Stewart and Holmes[21] The direction of the subjective movements were so constant that they were led to regard this as of serviceable diagnostic value They found that

> (1) In both intracerebellar and extracerebellar tumors the sense of displacement of external objects in front of patients is from the side of the lesion to the opposite side. Thus if the tumor be on the left side, the apparent movement of objects is from left to right.
>
> (2) In intracerebellar tumors the subjective rotation of oneself is always from the side of the lesion to the healthy side, that is in the same direction as the apparent movement of external objects
>
> (3) In extracerebellar tumors the subjective rotation of oneself is always from the healthy side toward the side of the lesion that is, in the opposite direction to that of the displacement of external objects

It will be noted that the apparent displacement of external objects is similar to that generally occurring in labyrinthine lesions and that the apparent rotation of oneself varies with the position of the tumor The relationships in intracerebellar tumors are the same as in labyrinthine lesions The diagnostic importance of the direction of subjective movements in cerebellar lesions has been questioned,[22] but even if not generally applicable they offer suggestions of value to aid in the diagnosis

ATAXIA AND DISORIENTATION

When we talk of ataxia we mean incoordination of movement—a disturbance in the particular organ itself When we talk of disturbance of orientation we mean that the organism has a special mechanism

---

[22] Lewandowsky Handbuch der Neurologie Berlin 1910 i 843

which adjusts the normal relationship of the body and its movements to its position or change of position in space The organism has numerous peripheral organs which signal in any change of position in a particular part—the ear, eye, muscles, joints, etc As the head is the most important segment of the body, so without doubt the labyrinth and the eyes are the most important receptive organs for the sensations necessary for orientation This is seen in the difficulties our labyrinthineless dogs have in walking with the eyes bandaged and the difficulties that deaf mutes and labyrinthineless dogs have in swimming In the latter case, in the absence of contact with solid bodies and in a medium in which appreciable differences of external pressure are excluded, the labyrinth is the only agency capable under all conditions of giving adequate information of the change of position of the head in space The action of the eyes is apparently less general and slower but this we will discuss more fully in a later paper

All these inflowing messages have to be correlated to produce a harmonious action of the whole organism—and probably the cerebellum is one organ which participates in this This correlation no doubt involves the afferent fibers which the cerebellum receives from the vestibular nerve, and its very close relationship with the vestibular nuclei in the pons and medulla While it is probable that the cerebellum participates in the integration of the impulses from the labyrinth with others from the periphery into the higher uniform function of maintaining a given orientation in space, yet certainly the cerebellum is not the sole central organ for orientation In passing it may be noted that it is this disturbance with the inflowing impulses from the periphery that is the scientific basis of attempts to localize particular cerebellar areas

In both cerebellar and labyrinthine lesions there is a deviation to one side in walking — to the side of the lesion if it is unilateral With the eyes open the patient corrects this, with the eyes shut, he may correct it, but usually, and especially in cerebellar cases, corrects too much, and then deviates to the sound side This deviation has nothing to do with ataxia It is a disturbance of orientation in space, is involuntary and appears in its most pronounced form in animals The sensation of such involuntary movements which is common in cerebellar disease must correspond to objective involuntary movements

When we consider the disturbances of orientation and the ataxia common to cerebellar and vestibular lesions we find, as the most obvious symptom, that the patient stands with the feet spread wide apart, that there is inability to stand on one foot, that the gait is uncertain and that the body tends to turn to the right or the left A discussion of the variations of muscular strength or of muscle fatigue does not come within the scope of this paper

Labyrinthine lesions differ from cerebellar (1) in the existence of Romberg's sign in labyrinthine lesions, (2) variations in the attitude of the head influence the lack of equilibrium of the body in labyrinthine and not in cerebellar lesions, (3) an affection of the labyrinth does not definitely involve those movements of isolated parts which result in dysmetria, (4) in labyrinthine disease movements of rotation or disorientation are not so readily perceived

(1) Romberg's sign The disturbances of equilibrium during walking and standing are increased, in labyrinthine disease, by shutting the eyes Suppression of visual control does not have the same effect in cerebellar lesions Sight is of less use to the cerebellar patient in maintaining the erect position although probably of some use and there are said to be cerebellar cases in which Romberg's sign is positive,[23] but as Dejerine insists, they are rare Romberg's sign is rare in destructive lesions of the cerebellum, as atrophy or sclerosis, rather frequent in abscesses, tumors or in lesions which affect other structures in their vicinity, and one may seriously question whether, in the cases of which Barany speaks, the cerebellum alone is involved, either directly or indirectly In labyrinthine disease standing on one foot is more difficult, especially on the foot on the side of the lesion This, however, is of no value if the patient has a peripheral sensory disturbance

(2) Relation of the attitude of the head to the disturbances (*a*) Goltz and Ewald showed many years ago that the pigeon deprived of its semicircular canals is not able to maintain its balance if the position of the sustaining base is changed This experiment has been repeated by many workers in other animals, and on it is based von Stein's goniometric test This consists in placing a patient with bandaged eyes on an inclined plane, the slope of which may be varied It is found that in labyrinthine cases the patient does not perceive, or perceives but slowly, the changing inclination of the plane and lets himself fall (*b*) In labyrinthine lesions the direction of falling, with the patient in the Romberg position, bears a direct relation to the plane of the nystagmus Barany has elaborated certain rules to show how the attitude of the head and the quick phase affect the fall, but, as we pointed out some years ago, there is a general rule for all positions of the head, namely that the patient falls in the direction of slow phase of the nystagmus And, as we have shown, even with the cerebellum injured, the labyrinthine reaction, nystagmus, attitude and falling, can be elicited by labyrinthine stimulation As Barany pointed out there is not the same connection between the direction of nystagmus and the direction of falling in cerebellar affections

(3) Lewandowsky[23] says that the particular character of cerebellar ataxia is the disturbance in standing and walking, *"Storung der Aufrechten Haltung und des aufrechten Ganges"* This results in those oscillations, that drunken gait, the titubation vertigineuse of Duchenne, so characteristic of cerebellar disease and not seen in labyrinthine lesions Further, the cerebellar patient shows dysmetria, his movements lack their proper proportion or measure in time and space, they are too rapid and too abrupt and miss their aim, the initial impulse is too strong, the speed too great, the arrest too late

The ataxia apparent after labyrinthine removal is due to a failure of the proper adjustment of the muscles necessary to the maintenance of equilibrium and orientation, owing to a failure in the accurate perception of the change of aspect of the head in space To put it briefly we might say that whereas the cerebellar ataxia is dynamic the labyrinthine is chiefly static

(4) We have sufficiently referred to the fact that in disease of the labyrinth the movements of orientation and disorientation are not perceived so readily On this subject no more remarks are called for at this time

---

[23] Lewandowsky Handbuch der Neurologie, Berlin 1910 i

In this discussion on the differential diagnosis of labyrinthine and of cerebellar disease we have not referred specially to the fact that in labyrinthine disease the physiologic action of the labyrinth can be shown, by the usual caloric and rotation tests, to be lost This fact we feel is so appreciated by neurologists and otologists that it is not necessary to dwell on it

We have therefore, in pure labyrinthine and pure cerebellar cases sufficient data at our disposal to decide the question of differential diagnosis It is difficult in the mixed cases If, however, we can exclude with these data the purely local labyrinthine and the purely local cerebellar we have gone some distance to locate the lesion, and can proceed intelligently to cases that involve both structures

---

THE RELATION OF HEAT TO SUMMER DIARRHEAS OF INFANTS *

ADRIEN BLEYER, M D
ST LOUIS

From observations that have been made on laboratory animals, diarrhea would not appear to be one of the characteristic effects of heat Dorlencourt and Schreiber produced death in dogs by exposing them to high temperatures without observing diarrhea Von Salle observed that diarrhea might or might not occur when young puppies were exposed to high temperatures Aron subjected monkeys to the direct heat of the sun, and caused death without observing diarrhea Hiller, in tabulating a large number of so-called heat-strokes in man, found that diarrhea occurred in less than half

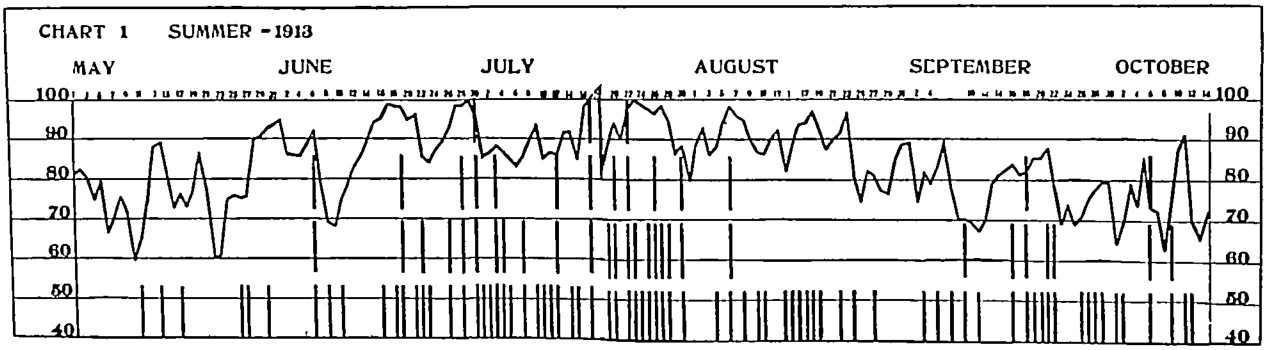

Chart 1 —Diarrhea and temperatures 1913 In this chart and Chart 2 the irregular horizontal line denotes maximum daily temperatures from May 1 to October 15 (U S Weather Bureau St. Louis) Each upright line at the lower margin indicates a case of acute diarrhea on a certain date additional cases are indicated by lines added above

TABLE 1 —SUMMARY OF CHART 1 SUMMER OF 1913 EIGHTY SIX ONSETS

Temperatures	No of Onsets	Per Cent
From 60 to 70	3	3 5
From 70 to 80	8	9 3
From 80 to 90	30	34 9
From 90 to 100	45	52 3

That heat is capable of disturbing physiologic health may, however, be admitted Disturbances in man may occur at temperatures of 75 F (Rubner) Disturbance of the normal respiratory exchanges denoting acceleration of the rate of metabolism has been noted at about this temperature (Sutton) If moderate exercise is taken, symptoms of heat retention may occur at 78 F (Haldane) As the environmental temperature rises, heat production becomes less (Langlois) A rise in body temperature may be produced by heat (Kleinschmidt, Heim, Genersich, John) Acetone and blood may appear in the urine, suppression of urine or even anuria may occur, there is a fall of blood pressure, the pulse rate rises, and the body surface becomes hyperemic, to be followed by pallor, unconsciousness and shock, completing the well-known picture of "heat-stroke"

TABLE 2 —SUMMARY OF CHART 2 SUMMER OF 1914 ONE HUNDRED AND THIRTY SIX ONSETS

Temperatures	No of Onsets	Per Cent
From 60 to 70	5	3 7
From 70 to 80	16	11 8
From 80 to 90	46	33 8
From 90 to 100	69	50 7

In the case of infants, these observations have peculiar significance because of the much greater surface area of the infant compared to body weight than is the case with the adult and the correspondingly greater need for rapid loss of heat This is in the proportion of about 3 1 That metabolism is more rapid in infants than in adults is shown by the relatively larger gaseous exchanges, the carbon dioxid coefficient normal to the adult rising in the infant almost to a point corresponding to the differences in surface area That the heat output of infants increases as the weight decreases was shown by Langlois, and more recently by Murlin and Hoobler in the case of weak and atrophic infants The latter writers found this difference greater in the second half of the first year than in the first half Variot and Lavialle observed that clothing may interfere sufficiently with heat-loss to be noted by the calorimeter This point,

TABLE 3 —SUMMARY OF CHARTS 1 AND 2, SUMMERS OF 1913 AND 1914 TWO HUNDRED AND TWENTY TWO ONSETS

* From the Department of Pediatrics, Washington University Medical School.

* Read before a meeting of the St. Louis Medical Society, May 31 1915

concerning the dangers of overclothing in summer, was the substance of a study by Helmholz, in which it was found that infants possess a capacity of withstanding high atmospheric temperatures provided they are not overburdened with clothes

It is not possible to say whether or not diarrhea is one of the symptoms of heat disturbance Very likely it is not, and it would seem that if a child who is suffering with what has been called heat retention is not fed, he will probably not have diarrhea, but if he is fed, and under such circumstances does have diarrhea, it would seem that the heat retention rather than the food was the cause of the diarrhea, because in the absence of high temperatures food does not exhibit this power, even when more or less highly contaminated with bacteria and their products (Rietschel) Liefmann's observation, that diarrheas occur three times as often in summer as in winter among breast-fed babies, has peculiar significance in this connection, as has also the observation of Holt and Park that diarrheas among tenement babies occur with great frequency among those fed condensed milk, which is not ordinarily considered a highly contaminated food

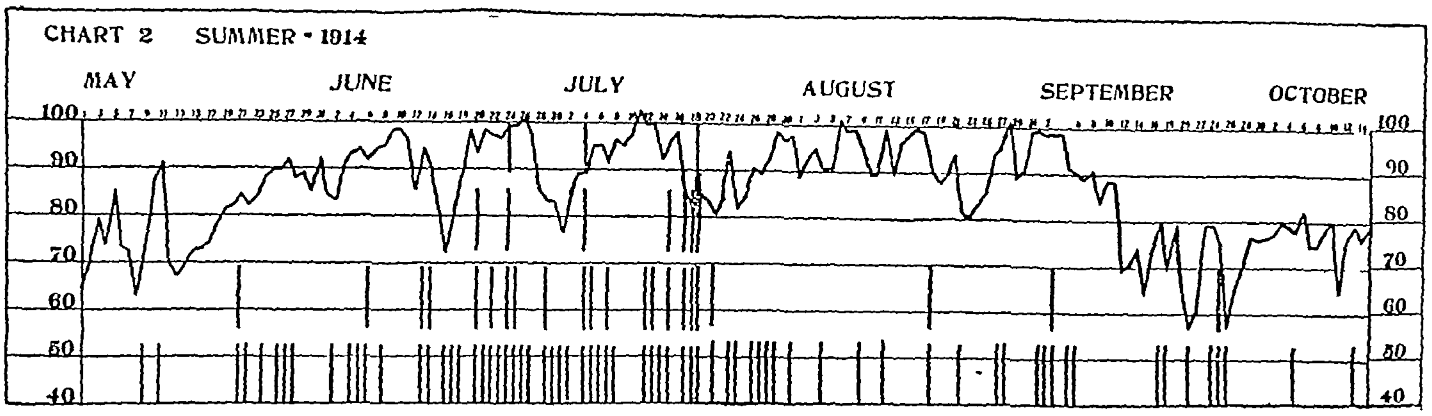

Chart 2 —Diarrhea and temperatures, 1914

Because of these somewhat contradictory observations a study was undertaken to determine whether or not, among the babies of the poor, a relation between the higher temperatures and the day of onset of diarrheas could be made out, no regard being paid to the feeding of the infants until the data collected had been summarized In the summer of 1913, eighty-six instances of acute diarrhea were collected in which the day of onset could be satisfactorily obtained[1] In the summer of 1914 an additional 136 cases were collected, sixty-two of them, I wish gratefully to acknowledge, by Dr T C Hempelmann

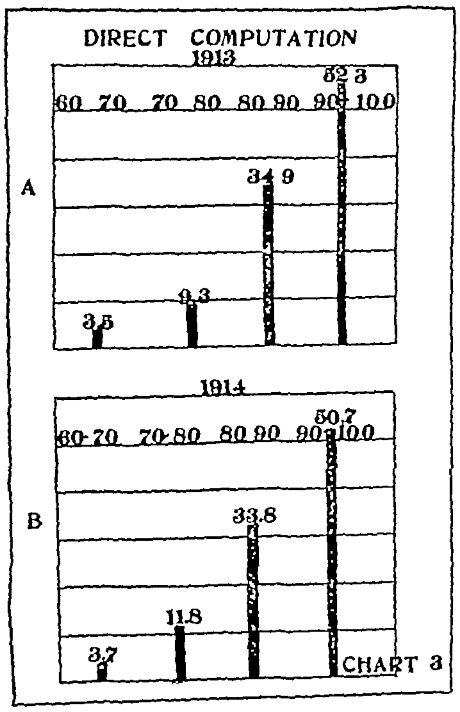

Chart 3 —Diagram showing the relation of heat to the onset of diarrheas among dispensary infants in St. Louis (Tables 1 and 2)

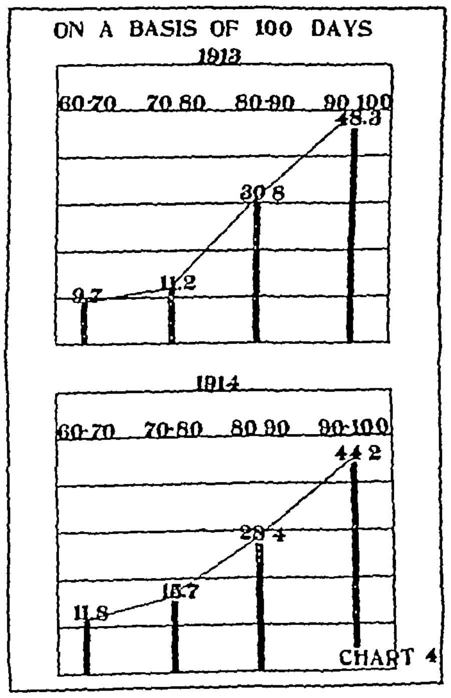

Chart 4 —Diagram showing that the relation of heat to the onset of diarrheas was not due to a coincident number of hot days (Table 4)

In collecting the cases, we were as careful as we could be to satisfy ourselves as to the health of the babies on the days preceding the disturbance of the bowel Only those babies previously well for at least two weeks were recorded, and if the onset of diarrhea had occurred more than two days before being reported by the mother, no record was made of it As to what constituted a diarrheic attack, five or more stools in one day in a baby accustomed to not more than two or three, or four stools, if definitely thin and watery, in a baby who, up to the day noted had had normal or well-formed stools, were, in either case, considered an acute onset Mild or questionable cases were excluded Practically all the babies listed were acutely sick, usually with fever and other symptoms of gastro-intestinal disturbance of the so-called "summer type" All the infants were in the first two years of life, about 80 per cent were in the first year

Summaries of Charts 1 and 2 are found in Tables 1 and 2, and a summary of the two summers in Table 3 By comparing the two summers, a singularly consistent relation between the higher temperatures and the day of onset of the diarrheas is seen Apparently, this becomes evident at 70 to 80, it is much stronger at 80 to 90 and quite marked at 90 to 100

After these charts had been drafted, the question arose as to whether the frequency of the diarrheic onsets was not really the result of a corresponding frequency of hot days The number of days at each respective temperature-group was therefore placed on a common basis of 100 days and, by preserving the ratios originally found, the effect on the incidence of onsets was again determined. Table 4 shows that this was not the case.

---

[1] The 1913 work was reported at a meeting of the St Louis Pediatric Society, June 12, 1914, but was reserved for publication until the work of another summer could be added to it.

SUMMARY

The studies reported in this paper in no way furnish evidence pertaining to the manner in which the influence of heat is exerted. They do show, however, in a large series of dispensary infants (222) developing acute attacks of diarrhea, that there was a direct relation between the degree of temperature and the onset of the diarrhea, over half (51.4 per cent.) of the babies becoming ill on days when the temperature was 90, although there were but 31 per cent. of such days in the two summers.

The observations were made among babies of the poor among whom diarrheas in summer are very prone to occur. Most of them were rationally fed, usually on some mixture of certified milk when breast milk was not available. It was especially interesting to find that thirty of them (13 per cent.) were exclusively breast-fed, and that twenty-two more were partially breast-fed, which is evidence that heat may very well influence the baby who is taking clean food. The knowledge gained of home conditions was not thorough enough to be worth tabulating, although home visits were made by nurses in practically every case. The reports of the nurses agreed very well with observations made at the clinic that a great majority of the babies were overburdened with clothing and suffered as do the babies of this class from lack of cleanliness and the usual surroundings of poverty.

A CASE OF VARICES OF THE MALE URETHRA

ERNEST G. MARK, M.D., and HARVEY E. McCARTHY, M.D., KANSAS CITY, MO.

We wish to report the following case which is of interest on account of its rarity and case history.

History.—E. M. G., aged 46, married, passenger brakeman. General history of no importance. No history of hemophilia. Twenty years ago he had gonorrhea once, followed a few years later by stricture for which perineal urethrotomy was done. He has had sounds passed at intervals since, followed by no reaction.

Present History.—July 28, 1914, while lifting a train box on a train he felt sudden pain in the region of the urinary bladder, followed by a desire to urinate. He voided urine, but as the act of urination was performed in the dark, he does not know whether any blood was passed. A few minutes later he noticed his clothing in the neighborhood of the genitals was damp, and on investigation found it quite bloody. He urinated five or six times during the night of July 28 without pain, noticed clotted blood at first followed by clear urine and then pure blood. He kept towels around the genitals for dressing and says that four towels were saturated with blood during the night.

Examination.—The patient entered the hospital the following day, at which time we were called in consultation by Dr. John G. Hayden, his attending physician. He was anemic and bleeding was independent of urination. His hemoglobin, as reported by Dr. Hayden, was 70 per cent. He exhibited no tenderness or pain over the renal region, bladder or urethra. The prostate was slightly enlarged but not hard or nodular. Clots presented at the external meatus and despite the administration of 10 c.c. of normal horse serum several hours previously by Dr. Hayden, stripping of the urethra provoked active bleeding.

After cocainization with a 2 per cent. solution containing quite a fair percentage of epinephrin, a cystoscope, 23 French, was introduced with slight difficulty. The use of the cocain solution was by reason of the fact that previous use of instruments had caused him much pain. The reason for the use of epinephrin is obvious.

Cystoscopy revealed no diseased condition in the bladder or posterior urethra. No clots were present and from neither ureter was any blood being passed.

After withdrawal of the cystoscope, the Mark urethroscope was passed with some difficulty to the bulbous urethra. On withdrawal of the tube nothing was found, with the exception of some areas of hard infiltration, until the anterior part of the scrotal urethra was entered.

In the region of the penoscrotal juncture on the roof of the urethra, a peculiar appearance was noted. An irregular, soft mass of a reddish-black color was seen projecting into the canal as a distinct tumor. This color disappeared entirely under air inflation, and irregular striae were noted, becoming yellowish under pressure with the exception of one point near the center, which retained the color of intense congestion. On close observation this was seen to be a small tear or rupture in the mucosa. On alternate distention and release of air, it became clear that the striae were vessels which were emptied of their blood under distention, and which immediately filled up on release of pressure. The point of rupture was unquestionably the source of hemorrhage. The desire to urinate was beyond doubt caused by the filling up of the anterior urethra with clotted blood, with subsequent back pressure.

There can be no question that the mass observed was a venous angioma.

But two cases of varix of the male urethra have, in so far as the search for material extends, been reported—one by Klotz (*New York Med. Jour.*, Jan. 26, 1895) and a case of Young's reported by Fowler (*Johns Hopkins Hosp. Rep.*, xiii, 91, 1906). The reports in full of these cases are given by Lewis and Mark ("Cystoscopy and Urethroscopy," p. 205).

626 Lathrop Building.

Transfusion by the Citrate Method in a Sixty-Hour-Old Baby with Melena Neonatorum.—In view of the interest manifested in the citrate method of transfusion, the following case is worth reporting. A girl baby, weighing 8 pounds, was delivered with low forceps because of an incompletely rotated head. The delivery was made without difficulty and with no apparent injury to the child. During the first fifty hours, the child was irritable and cried. It then passed a small amount of bright blood from the bowels, and three hours later a larger amount of dark blood, at which time it was given a subcutaneous injection of normal horse serum. During the next seven hours eight or ten stools were passed composed exclusively of dark blood. The ears were colorless, lips and finger-nails cyanotic, and the child was having difficulty in breathing. The median basilic vein of the baby was raised through a small incision, and 60 c.c. of citrated blood were injected with a record syringe and needle. The child's color was noticeably improved in both the ears and the lips, respirations were easy, and for the next two hours it slept. During the next few hours two more stools of dark blood were passed, evidently that remaining in the bowel at the time of transfusion. From that time recovery was uneventful. The blood used in transfusing was prepared by placing in a sterile container 10 c.c. of sterile 2 per cent. sodium citrate solution and adding to that 100 c.c. of blood removed from a vein in the father's arm with a syringe and needle. The father's veins were small, and the needle introduced did not allow blood to escape rapidly enough, so a syringe was used to facilitate matters, the blood being immediately mixed with the citrate solution.—H. WOLTMANN, M.D., Mansfield, Ohio.

Morbid Introspection.—The movements of the body machinery do not often rise into the consciousness of the normal man, but are a continuous moving picture show to the neurasthenic.—*Monthly Health Letter.*

New Instruments and Suggestions

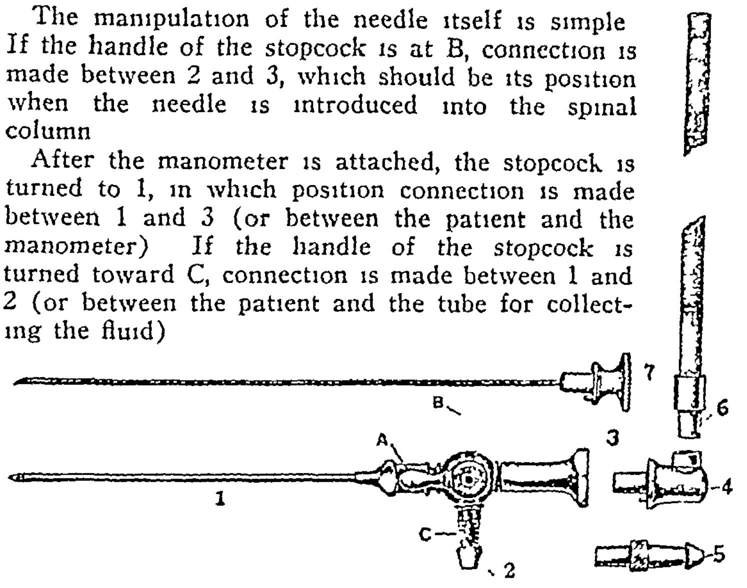
AN IMPROVED LUMBAR PUNCTURE NEEDLE

Julian Mast Wolfsohn, M S , M D , San Francisco
Instructor in Neurology, Leland Stanford Junior University, School of Medicine

Since intraspinal medication is becoming such an important adjunct in the therapeutics of syphilis of the central nervous system, accuracy and ease of administration of the drug used are all important Therefore a modification of the lumbar puncture needle described by me in The Journal, April 19, 1913, p 1204, has been perfected This new needle has many advantages over the old, in that (1) an assistant is not needed to hold the manometer, (2) there is a three-way stopcock which rotates through only 180 degrees, and (3) the administration of intraspinal medication is facilitated The special features of the former needle are to be found in this new needle

The manipulation of the needle itself is simple If the handle of the stopcock is at B, connection is made between 2 and 3, which should be its position when the needle is introduced into the spinal column

After the manometer is attached, the stopcock is turned to 1, in which position connection is made between 1 and 3 (or between the patient and the manometer) If the handle of the stopcock is turned toward C, connection is made between 1 and 2 (or between the patient and the tube for collecting the fluid)



Improved lumbar puncture needle.

For injection the Lüer syringe is inserted directly into 4, or if another container is used, it is connected by rubber tubing to 5, which is inserted into 4, and the fluid allowed to flow by gravity into the subdural space

2502 Fillmore Street

A POLYCHROME STAIN WITH ADVANTAGES OVER THE GIEMSA*

Frank A McJunkin, M D , Boston

Numerous modifications of the Romanowsky stain have been used in microbiology and hematology Of these the Giemsa stain is useful in the staining of smear preparations for spirochetes and protozoa, while the Leishman, and Wright's modification of the Leishman are of greater value for the staining of blood

In the stain described here, the method of ripening the methylene blue used by Novy and the method of obtaining solution of the dyes used by Giemsa are made use of It has the advantage over Novy's method that a single permanent solution is used, and over Giemsa's method that the stain is of greater intensity and much less expensive

THE ROMANOWSKY STAIN

A solution of eosin and methylene blue, made by adding an aqueous solution of eosin to a freshly prepared aqueous solution of methylene blue, stains nuclei blue and cytoplasm red However, when the solution of eosin is added in the right proportion to a slightly alkaline methylene blue solution that has stood for a number of days or that has been heated, the staining is different The nuclei of the cells treated with such solutions are red, while the cytoplasm is blue This color reaction characterizes the Romanowsky solution and all subsequent modifications of it. The structures of smear preparations stained in this way not only show a beautiful color differentiation but they are also heavily stained This color differentiation and the intense staining of structures make the stain of the greatest value in the study of protozoa and other organisms

The staining characteristic of such ripened alkaline methylene blue solutions was noted by Romanowsky in 1891, and since then a very large number of modifications of his method of preparing the staining solution have been described The red staining of the chromatin material by polychrome solutions received several explanations, and by some investigators was ascribed to a single chemical compound to which the term "azur" was applied More recent chemical investigation indicates that more than a single compound formed by the action of dilute alkalies on methylene blue has this property

THE GIEMSA STAIN

Giemsa states that he has prepared in a pure form the substance that stains the chromatin red but the method of preparation, so far as I know, has not been published It may be purchased from Grübler & Co and their agents under the name of Azur 1 The Azur combined with methylene blue and eosin and dissolved in methyl alcohol and glycerin gives a single solution which, when added to water, makes an excellent polychrome stain The Azur 1 and the solutions made from it are expensive, but the simplicity of their application and the good results obtained have led to their extensive use

THE NOVY STAIN

A method of preparing polychrome methylene blue has been devised by Novy and used in the bacteriologic laboratory in the University of Michigan for the past ten years One gm of methylene blue (Grübler's B X), 0.25 gm of sodium carbonate (anhydrous), 50 c c of twice distilled glycerin and 50 c c of distilled water are placed in a 500-c c beaker provided with a mechanical stirrer The temperature is then raised to 88 C by heating with a Bunsen burner and kept between 87 and 89 C for one hour while the solution is constantly stirred at the rate of about 200 revolutions per minute During the heating, distilled water is added in sufficient amounts to make up the loss from evaporation, and the solution finally made up to the original 100 c c

The polychrome methylene blue prepared in this way is placed in a dropping bottle "A," while a 1 per cent solution of methylene blue in 50 per cent glycerin is placed in a second dropping bottle, "B," and a one-half aqueous solution of eosin in a third bottle, "C" At the time of making each stain, about 9 drops of "A," 7 drops of "B" and 7 drops of "C" are added to 15 c c of distilled water The number of drops of each must be ascertained for each new batch of polychrome methylene blue solution Excellent results may be obtained by this method The polychrome methylene blue solution steadily changes on standing, as the methylene blue is in a slightly alkaline aqueous solution

THE POLYCHROME STAIN FOR PROTOZOA DESCRIBED HERE

In this stain the polychrome methylene blue, the methylene blue and the eosin are combined in a single solution by using methyl alcohol and glycerin as solvents In this way there is obtained a single solution which is used like the Giemsa, which stains nuclear material more intensely than the Giemsa solution, and is less expensive and easily prepared (The stain already prepared may be obtained from Bausch & Lomb Optical Company, Rochester, N Y)

In preparing the polychrome methylene blue solution, first measure accurately from a buret into a 500 c c beaker 50 c c of deci-normal sodium carbonate The carbonate solution is titrated against a standard acid using as an indicator a 1 per cent alcoholic solution of methyl red and diluted until there is no factor To the carbonate solution add 1 gm of methylene blue (Grubler's B X) and 50 c c of glycerine

---

* From the Pathological Laboratory of the Boston City Hospital

(Merck U. S. P.). The glycerine may be measured in a 100 c.c. graduate. Place the beaker in a water bath and equip with a mechanical stirrer which is run at the rate of about 200 revolutions per minute. A thermometer is placed in the solution in the beaker and the temperature raised to 87 to 89 C. where it is kept for one hour and thirty minutes. The water in the bath outside the beaker should be regulated at 94 to 96 C. At the end of forty-five minutes, add 20 c.c. of distilled water to the stain. At the end of the hour and thirty minutes, remove the beaker from the water bath and pour its contents while warm into a 100 c.c. graduate. Add 5 c.c. of distilled water to the beaker to remove any carbonate that may have precipitated out and pour this into the graduate also. Let the stain stand in this graduate and measure into a second graduate enough methyl alcohol (Merck reagent or Kahlbaum acetone free) to make the total volume 100 c.c. when added to the stain. This methyl alcohol is poured from the second graduate into a 4-ounce bottle and 0.75 gm. of methylene blue (Grübler's B. X.) and 0.25 gm. of eosin (Grubler's yellowish water soluble) added to it. Shake the bottle to secure solution of the methylene blue and the eosin in the alcohol. After the dyes are completely dissolved in the methyl alcohol pour the polychrome methylene blue solution from the graduate into the bottle. The volume of dye in the bottle is now 100 c.c. The weights of the dyes must be accurate and the glassware free from acid.

In using different samples of eosin (Grubler's yellowish, water soluble) a preparation is occasionally met with that is not satisfactory. The stain made with such an eosin stains the red blood corpuscles a blue that cannot be washed out with water. For this reason it is preferable to use an eosin that has previously been found satisfactory in making polychrome staining solutions.

METHODS OF USING THIS STAINING SOLUTION

Application to Smears for the Demonstration of Protozoa and Bacteria.—Smear preparations may be made on either slides or cover-glasses and they may be fixed in a variety of ways, but fixation in equal parts of absolute alcohol and ether for from ten minutes to a number of hours gives perhaps the best results. Distilled water is placed in a staining dish, and to this 1 drop of the stain per cubic centimeter of the water is added. Cover-glass preparations are floated on the solution as soon as the dilution is made, and stained for from thirty to sixty minutes. Trypanosomes, for example are well stained at the end of half an hour, while about one hour is required to stain *Spirochaeta pallida* heavily. The preparation is removed from the stain, and any excess of blue is washed out with distilled water. This may require from one to several minutes in order to bring out the pink color in red blood corpuscles. After washing, the preparation is dried in the air and mounted in acid-free balsam. Slide preparations are best stained by inverting them and allowing the very end of the slide to rest on the end of an oblong Petri dish without cover (a dish the length and width of a slide and about 2 cm. high). The slide is placed in the solution in this way so as to bring the preparation side as near to the surface of the stain as possible. The preparations after staining and washing are dried in the air when they may be examined directly with oil, or they may be mounted in acid-free balsam.

Application to Sections of Tissue for the Demonstration of Protozoa, Bacteria, the Megakaryocytes of Bone Marrow, Etc.—It is more difficult to obtain Romanowsky staining in tissue preparations than in smears. The tissue is cut into pieces not more than 2 mm. thick and placed in 1 part of absolute alcohol and 2 parts of saturated aqueous solution of mercuric chlorid for at least twenty-four hours or it is fixed in 10 per cent. dilution of liquor formaldehydi. If the latter is used as the fixative shrinkage during the imbedding process should be reduced to a minimum. Sections not more than 3.5 microns are cut from paraffin blocks and if mercuric chlorid alcohol was used as a fixative the mercury is removed with iodin. The staining is carried out just as in the case of smears, except that the preparations are allowed to stain over night. After staining, the preparations are washed with distilled water for one minute, and with a cloth or filter paper the excess of water is wiped from the slide or cover-glass about the preparation, which is then dehydrated in xylene containing 5 per cent. of absolute alcohol and 1 per cent. colophonium. The solution in a small dish is renewed several times until by agitation all the visible water is removed from the preparation, which is allowed to remain in the solution from three to six hours until the desired differentiation is obtained, after which it is passed through two changes of xylene and mounted in acid-free balsam. If the nuclei are not the proper red color and there is an excess of blue in the preparation the slide is placed in the sunlight for several hours, as has been recommended by Mallory.

Application to Blood Films. A Polychrome Stain for Blood.—For the routine staining of preparations of blood, the method should be simple and quick and yet bring out all the structures present. For these reasons the stain described above is not applicable to blood films for the usual differential counting of the white cells, inasmuch as the preparation requires separate fixation and prolonged staining. If this stain is at hand however it will be found that an excellent blood stain that is permanent may readily be prepared from it. (The stain already prepared may be obtained from Bausch & Lomb Optical Co., Rochester, N. Y.)

A majority of the samples of commercial polychrome blood stains obtained, do not give the polychrome staining, the nuclei of cells are bluish when films are stained with them in the usual way. Such stains do not bring out the "azur" granules of the endothelial leukocytes. These deficiencies are due in part at least to a failure to adjust properly the reaction of the staining solution. To differentiate the cells that are found in the blood stream, a stain that gives uniform results should be used. The reaction of the polychrome blood stain here described is accurately determined and the staining properties of all samples examined up to the present are constant.

To prepare the Polychrome Stain for Blood, place in an acid free bottle 50 c.c. of the Polychrome Stain for Protozoa and add 250 c.c. of methyl alcohol (Merck Reagent or Kahlbaum acetone free), 0.34 gm. of eosin (Grübler's yellowish, water soluble) and 2 c.c. of half-normal hydrochloric acid (measured accurately from a buret).

To apply the blood stain, the alcoholic solution is placed on the slide or cover-glass in sufficient amount (two drops for a cover-glass and eight drops for a slide) to cover completely the unfixed film for one minute, when twice as much distilled water as stain is added and allowed to act for five minutes. The preparation is washed with distilled water, dried in the air and examined directly with the oil immersion, or it may be mounted in balsam. The red blood corpuscles stain an orange. The leukocytes are well differentiated. The nuclei of all the white cells are red. The cytoplasm of the lymphoblastic cells is a robin's egg blue and free from granules (unless the preparation is overstained), that of the endothelial leukocytes has a trace of blue and a number of reddish-staining granules, while the cytoplasmic part of the neutrophils has no blue and is thickly studded with the neutrophil granules.

Exhausted Orange Peel for Chronic Constipation.—At a recent meeting of the Societe de therapeutique, G. Rosenthal stated that exhausted orange peel had been used with success in the French army for the mechanical treatment of chronic constipation as a substitute for agar-agar. Fresh orange peel is boiled for half an hour in water. The decoction is decanted, and may be used for flavoring mixtures or liquid dentifrices. The marc is then again boiled for thirty minutes in a fresh portion of slightly sweetened water, drained and dried on a plate, when it is ready for use. In addition to the mechanical action of the swelled cellulose giving the necessary consistence to the contents of the alimentary tract, it also stimulates the flow of bile.—*Journal de pharmacie et de chimie*, 1915, xii, 234.

Therapeutics

ANGINA PECTORIS

The chief indications in the management of angina pectoris, aside from the treatment of the attacks themselves, are to remove every possible cause favoring the onset of the attacks and to treat the disease of which angina is frequently found to be only a manifestation Soca for a long time has been convinced that the absorption of toxic products during metabolism is an etiologic factor of importance in the pathogenesis of all functional troubles of the heart and of the aorta This conviction led him to question whether this might not also apply to the attacks of angina pectoris, and to the employment of what he calls the "detoxicating" treatment for their prevention The results of this treatment answered his question in the affirmative and convinced him that intoxication is always present in angina pectoris His position is that this theory is in no way contradictory to the accepted theories of the etiology of the disease, but that it supplements them

During the last ten years Soca[1] has seen 123 anginal patients, eighty of whom have been followed for a sufficient time to warrant therapeutic conclusions At the beginning of the treatment, in a few severe cases, bloodletting or wet cupping was used Amyl nitrite was used in a few cases for the relief of a severe attack, but neither of these procedures comprises a part of the regular treatment Nitroglycerin and the nitrites were not used at all, and no special treatment for hypertension was given except in syphilitics and patients with atheroma In such cases potassium iodid was used

Whenever the underlying disease causing the trouble could be discovered, it was of course treated The other treatment consists of diet, diuretics and rest

For the first day the patient who has a history of angina pectoris attacks is given nothing but water On the second day milk is given in quantities varying from 1½ to 3 quarts Nothing but milk is allowed for from one to three weeks, according to the severity of the case and the response to treatment In the milder cases, at the end of a week, soups made of milk and various kinds of cereals are added and continued for one or two weeks At the end of this time cooked vegetables without salt are added and continued for a month or two Then eggs and a small amount of meat are allowed Milk still remains the basis of the diet, and no salt is added to the food This remains the permanent diet, except that it is discontinued for one week each month, during which time milk alone is taken If attacks recur, the milk diet is resumed at once Some diuretic was always given, such as theobromin salt

Absolute rest was not found to be necessary in any but the severest cases Moderate exercise, including walking, was allowed, but insistence was laid on the avoidance of hasty exertion

At the end of the first week of this treatment, or before that time, pain had invariably been diminished or had stopped Twenty per cent of the cases showed no further amelioration In the others (80 per cent) there was decided amelioration, and in more than half of the cases there was relative or absolute cure, as shown by freedom from attacks even after exertion

It is well known that sudden emotion and overexertion are among the most frequent immediate causes of attacks of angina This is probably due to the fact that they cause a sudden increase of arterial tension Huchard pointed out that any medication which reduced arterial tension usually relieved, to a greater or less extent, the sufferings of patients afflicted with angina While Soca calls the treatment he suggests a "detoxicating" treatment, it is also one which tends permanently to lower the high blood pressure usually present It is rational and quite in line with the best modern treatment of high blood pressure, which attempts to lower this pressure permanently or at least to keep it from increasing by hygienic and dietetic measures, aided by the use of as little vasodilating medication as possible

NEURASTHENIA—SUPRARENAL INSUFFICIENCY

The suggestion that neurasthenia, like hysteria, needed explanation, and that many of the symptoms of this condition could be explained by a subsecretion of the suprarenals was made by Osborne,[1] in several discussions on the subject of internal secretions, and was distinctly described by the same author[2] in an article published in 1910, in which he says, "It is possible that neurasthenic conditions and conditions of chronic low blood pressure, without tangible circulatory excuse, may be due to an undersecretion of the suprarenals " Recently, Tom A Williams[3] has described what he terms the "syndrome of adrenal insufficiency," which is really a form of nervous tire or nervous prostration, or, in more recent years, the fashionable "neurasthenia " Williams thinks that the term neurasthenia is only "a convenient cloak for failure to investigate a case sufficiently " In other words, there must be some tangible cause for the prolonged or persistent condition once called nervous prostration and now neurasthenia

It must, of course, be allowed that physical tire may cause circulatory weakness and prostration, and that mental tire may cause sleeplessness, loss of appetite, and thus a marked insufficiency in the recuperative power of the body without perhaps any special disturbance of any organ or gland On the other hand, persons who are always neurasthenic, always subnormal, without any special disease, should be subject to classification even more readily than is the neurotic individual The typical neurotic generally has, if not always, disturbance of the thyroid gland The typical neurasthenic probably generally has disturbance of the suprarenal gland on the side of insufficiency The blood pressure in these neurasthenic patients is almost always low for the individuals, and their circulation is poor Often the activities of the internal organs are impaired, although there may be no discoverable organic disease Mental exertion, even the simplest, often causes so much weariness and exhaustion as to be prohibitive, that is, such exertion must be forbidden A vasomotor paralysis, often present, allows chillings, flushings, cold or burning hands and feet, drowsiness when the patient is up, wakefulness on lying down and hence insomnia The nutrition may be fair or even good, and the weight may be normal There may be more or less tingling or numbness of the extremities

[1] Osborne, O T The Therapeutic Application of the Organic Extracts The Journal A. M A, March 23, 1901, p 796, Med News New York, July 12, 1902, ibid, April 4, 1903

[2] Osborne, O T Disturbances of the Internal Secretions Clinically Considered The Journal A M A Feb 26 1910 p 670

[3] Williams, Tom A The Syndrome of Adrenalin Insufficiency, The Journal A M A, Dec 19, 1914, p 2203

There is not much doubt that the cause is disturbance of one or more internal secretions, but just which glands are at fault is difficult to determine Testicular and ovarian disturbance, especially on the side of deficiency, are known to cause general depression, hysteria, hypochondriasis, melancholia and disturbances of the digestive secretions A disturbance of the thyroid secretion may cause in one patient hysteria and in another patient depression, or both conditions may occur in the same patient at different periods That very large mammary glands, in women who are not pregnant and who are not lactating, may disturb the system has not yet been proved Many girls and women, however, who are not well and strong, whose flesh is flabby, who may either be overweight or underweight, and who have the mammary glands excessively large, may be disturbed by an internal secretion of which we as yet know little Pituitary disturbance may affect the cerebral activity The pineal gland seems to have an important secretion Many of the symptoms of physical and mental tire, with low blood pressure, especially if accompanied by increased pigmentation anywhere on the skin, may be due to insufficiency of the suprarenals

Williams comes to the conclusion that many patients who present the well-known symptoms termed "neurasthenia" with low blood pressure, with loss of mental elasticity, with both mental and physical depression with the fear that they cannot now accomplish their usual good mental work, with the story that they have "lost their nerve," in the phraseology of the times, with the fearfulness of making wrong decisions, and with a vascillating and indecisive frame of mind, are many times suffering from an insufficiency of the suprarenals He finds that the administration of the dried suprarenal gland, in tablets of from 2 to 4 grains, two or three times a day, has caused improvement in many cases

Any sensible suggestion is worthy of trial in this troublesome neurasthenia, especially as such patients readily acquire the sanatorium habit and become more depressed Physical and healthy mental exercise is good for these patients Generally an increased protein diet does them good, as many of them have been, for one reason or another, reducing their meat, fish and egg intake

It should be urged that for the supposed suprarenal insufficiency it is not sufficient to give the blood-pressure-raising substance of the suprarenals, but the whole gland must be fed Just how much valuable activity is absorbed from the suprarenal when fed has not been determined Cases are on record in which feeding of this gland has seemed to cure or cause an amelioration of the symptoms of Addison's disease Williams in many instances has found the blood pressure raised by the administration of this glandular substance by the mouth

As the posterior lobe of the pituitary gland has been found to furnish a stimulant to the suprarenals it might be well to consider administering a small dose of this gland in conditions of subsecretion of the suprarenals, especially as this part of the pituitary furnishes a vasopressor substance

As yet we have not sufficiently recognized the fact that all of the internal secreting glands may be subject to the same conditions of hypersecreting and undersecreting which are so well recognized as occurring in the thyroid gland It is quite probable that many unexplained cases of hypertension are due to an increased suprarenal secretion, and it certainly seems more than likely that the condition of chronic hypotension is due to a subsecretion of the suprarenals

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies"

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation but that, so far as known, it complies with the rules adopted by the Council.

W A Puckner, Secretary

SEROBACTERINS (See N N R, 1915, p 329)—The following dosage form has been accepted

H K. Mulford Co, Philadelphia.

Scarlatina Strepto Serobacterin Mulford (Therapeutic)—*(Sensitized Scarlatinal Streptococcic Vaccine)*—Marketed in packages of four syringes containing respectively, 250 million 500 million, 1,000 million and 2 000 million killed sensitized streptococci

QUININE DIHYDROCHLORIDE—Quininae Dihydrochloridum, $C_{20}H_{24}N_2O\text{-}2HCl$—The dihydrochlorid of the alkaloid quinine

Actions Uses and Dosage—The same as those of other salts of quinine Since quinine dihydrochloride is a very soluble salt of quinine, its use has been proposed where concentrated solutions of quinine are wanted, as for subcutaneous injections and similar purposes

Ampules Quinine Dihydrochloride Mulford 0 24 Gm—Each ampule contains 0 24 Gm (3¾ gr) quinine dihydrochloride in 1 Cc of sterile solution Prepared by H K. Mulford Co Philadelphia

Ampules Quinine Dihydrochloride Mulford, 0 5 Gm—Each ampule contains 0 5 Gm (7¾ gr) quinine dihydrochloride in 1 Cc of sterile solution Prepared by H K. Mulford Co Philadelphia.

Quinine dihydrochloride occurs as a white powder having a very bitter taste. It should be kept in well closed containers protected from light. It is soluble in about 0 6 parts of water and in about 10 parts of alcohol at 25 C It is almost insoluble in chloroform and ether Its aqueous solution is strongly acid to litmus

Quinine dihydrochloride responds to the usual identity tests for quinine and chloride. It should be practically free from sulphate and from barium.

PURIFIED TRICRESOL, Mulford—A mixture of isomeric cresols, corresponding closely to Cresol U S P

Manufactured by H K. Mulford Co Philadelphia No U S patents or trade marks

Purified tricresol Mulford, is soluble in 50 parts of water at 25 C it is free from bases such as pyridine and from hydrocarbons Its phenol coefficient, determined by the U S Hygienic Laboratory method is not less than 2 5 (the exact value is stated on each package) and of a phenol toxicity determined by the method of Hale not greater than 150 per cent (the exact value is stated on each package)

IODOSTICKS (Iodine 60 per cent and Potassium Iodide 40 per cent)—Wooden sticks 1½ inches long, tipped with a mixture of iodine 60 per cent and potassium iodide 40 per cent., packed in amber glass containers Each stick is to be used but once

(Accepted for inclusion with the appendix to New and Nonofficial Remedies)

Prepared by Antiseptic Supply Co New York

IODOAPPLICATORS AND IODOAPPLICATORS, SPECIAL (Iodine 60 per cent and Potassium Iodide 40 per cent)—Wooden sticks 6½ and 12 inches long, respectively, tipped with a mixture of iodine 60 per cent and potassium iodide 40 per cent, packed in amber glass tubes Each stick is to be used but once

(Accepted for inclusion with the appendix to New and Nonofficial Remedies.)

Prepared by Antiseptic Supply Co New York

FATS IN METABOLISM

Our increasing information in respect to the phenomenon known as the specific dynamic action of the foodstuffs in metabolism has repeatedly been discussed in The Journal If the basal level of metabolism, that is, the transformation of energy in an individual at complete rest and in the absence of food, is carefully determined by the methods of either direct or indirect calorimetry now successfully in use in this country, remarkably constant values are obtained from hour to hour The fundamental resting energy requirement in each case is thus shown to be surprisingly uniform, and when suitable allowances are made for inequalities of size, the basal metabolism per unit of the individual appears likewise to be quite comparable between different persons The scientific basis for estimating the minimal energy requirement of the healthy, normal individual is thus established

Ingestion of food is the occasion for an increase in the metabolism The cause of this "specific dynamic action" of the foodstuffs has been a subject for investigation and theorizing for many years Repeated attempts have been made to explain, on some general underlying basis, the known phenomena of this increased heat production attending the intake of foods Hypotheses postulating the increased work of the digestive glands and the alimentary apparatus, the circulatory and the excretory organs, entailed by food intake, have all been found inadequate to account for the known facts Again, it has been suggested that the products of digestion act as stimulants to the body cells, and thus induce chemical changes with a liberation of heat Attempts have even been made to designate these metabolic stimuli as being definitely of an acid character Thus it was hoped to account for the heightened basal metabolism in certain diseases on the ground of an undue production of acid products as a result of the nutritive disorder

It is becoming more and more apparent that the potent factor in increasing heat production in the ways just cited lies in increasing the metabolites available for cell nutrition Added evidence of this has lately been furnished by Murlin and Lusk[1] of Cornell University Medical College Carbohydrates like glucose, and the amino-acid digestion products of proteins are readily absorbed, and when they are consumed, a rise in heat production follows promptly Fats differ from the other foodstuffs in that the progress of their absorption is somewhat slower The fat content of the blood shows a gradual rise after ingestion of fats, and may not reach its maximum until several hours after the intake of the meal Murlin and Lusk have found that the heat production of the organism shows a similar gradual rise after a meal of fat—an increase which may be regarded as parallel to the progressive influx of fat globules into the blood stream from the thoracic duct They note that the ingestion of fat does not change the quantity of heat produced from protein and glycogen, but that the increased metabolism is at the expense of the fat ingested It is evidently not a single factor or mechanism like the alimentary process which is here concerned If glucose is ingested at the time of the highest fat metabolism, the heat production undergoes a second increase by the same quota which glucose alone would have increased metabolism The respiratory quotient shows that glucose and fat were being oxidized together Furthermore, when glucose and the amino-acid glycocoll, typical of a nitrogenous digestion product, are given together so that their molecules enter the circulation at the time of the height of fat absorption, the increase in metabolism is very nearly equal to the sum of the increases which each of the three materials would have induced alone In the interesting details revealed by their work, Murlin and Lusk see a vindication of the opinion of that master student of nutrition, Carl Voit, that the height of the heat production is determined by the quantity and quality of the materials brought to the cells by the blood

THE MADNESS OF SPORT

A dictionary defines sport as a "particular game or play pursued for diversion, especially an athletic or outdoor game or amusement" It then proceeds to give another definition of the word as "a mockery or object of derision" Any one who contemplates some of the performances in this country which have lately been dignified with the name of sport may wonder in which of the foregoing categories these exhibitions deserve to be classed The public press has spread broadcast the story of a recent automobile contest in which the winner exceeded an average speed of 100 miles per hour for more than three hours The reports of the finish tell that "the driver, overcome by the roar of his machine, was unable to hear for several minutes and acted otherwise like a deranged man"

---

[1] Murlin J R and Lusk Graham Animal Calorimetry, Twelfth Paper, The Influence of the Ingestion of Fat, Jour Biol Chem, 1915 xxii, 15

This type of performance also reminds one of the dangerous and thrilling midair stunts in which a few widely advertised aeroplane enthusiasts have engaged, sometimes at the sacrifice of their own lives

Some of this modern sport mania seems to us to deserve the condemnation which we have not hesitated to apply to certain features of the competitive athletics practiced in American institutions of learning or by other groups of young men[1] No one will gainsay the value and pleasure of outdoor exercise graduated to suit the needs of every individual throughout life But the species of overdoing called for in the intense competition of the great contests of our schools and colleges can no longer be defended by platitudes regarding the alleged psychologic value of its competitive features The time has come when statistics regarding latent athletic injuries must be reckoned with and the lives of our youths safeguarded by making a distinction between sane sport and insane participation in the intolerable strain of competitive games of the extreme type The desire to win at any cost must be criticized, not only from the standpoint of unethical practices between opponents, but also with consideration of the insults — sometimes almost intolerable insults — which the strain of training and final competition may place on even normal organs such as the heart Dr Willson of Philadelphia sounded a warning which will be endorsed by many an unbiased observer of what is occurring on our athletic fields, when he said "Trainers should be taught just what the collapse of today means in the future of the athlete Some day the college authorities must of necessity conclude that no form of athletic event is sane that demands of the participants the semiconscious state of heart exhaustion at its conclusion"[2]

Dr Willson presents the issue squarely when he insists that the wisdom or unprofitableness of college and schoolboy competitive athletics must be determined by (1) the ultimate result of public competitive athletics on the physical health and lives of the participants, and (2) the possibility of determining the genuine physical integrity of the proposed participant or his lack of the same, especially with respect to his heart These are criteria which the enthusiasts for the severest types of competitive sports must sooner or later face, unless they will maintain, like some of the advocates of war, that struggle develops some unique human virtues which overbalance any bodily harm

The trainers of athletes are recruited from among individuals who have little or no appreciation of the physiologic principles involved in muscular performance Their aim is comprised in the cry of "win at any cost," and their own prestige hinges on the success of their proteges in competitive or record-breaking contests School and college authorities are singularly indifferent to the question of physiologic fitness and consequences in the case of students who are, in a sense their wards Any one who has given attention to the subject through unbiased channels can readily convince himself that little really useful information is ordinarily available among athletic associations and college groups regarding the physical condition of their members, except so far as it is exemplified in athletic performance They need to be reminded in an emphatic and authoritative way, in the words of Willson, that "no form of athletic event is sane that demands of the participants the semiconscious state of heart exhaustion at its conclusion" Has not the time arrived to call a halt on "insane indulgence" in sport?

And what shall be said of the reckless forms of sport which seem to bewitch by the terrible dangers that they court? Little is gained for the progress of motoring or the science of flying by the daredevil types of performance which are a challenge to fate They seem to have outdone the major sports in which at least any danger involved is not the chief interest to the spectator Let us cease to dignify the recent exhibitions with the designation of sport One editorial writer has expressed it by stating that events which depend for thrill on the nearest possible approach to death by the actors in them represent the degeneracy which overtakes sport and makes madness of it

GARMENT MAKING AND SOME DANGERS TO HEALTH

The solidarity in health matters that exists among all classes is made manifest by the results of an investigation of the garment making trades[1] Attention to this phase of social betterment is more than merely philanthropic or charitable in the ordinary sense of the word, it also has a wide social significance Improvements in the conditions under which such workers labor not only do good for those actually engaged in the occupations investigated, but also are of distinct benefit to the whole community in its definite limitation of the spread of disease

Garment making has passed almost entirely out of the hands of the family and of the numerous small tailoring establishments which used to supply most of the demands in this line, to become the task of large concerns in which numbers of workers are necessarily employed often in very crowded quarters The health of these workers, in addition to its importance as a matter of civic sanitation and the reduction of the municipal mortality and morbidity rates, is of special significance from the fact that large numbers of the community are brought indirectly into contact with these workers through the garments which they have handled rather intimately in the making The suggestion that tuberculosis is undoubtedly the most serious disease prevalent among the garment workers is rather startling In the revolution of the trade, garment making has in recent years passed largely out of the hands of women into those of men, so that the observation that consumption is over three times as frequent among the males as among the females in the trade adds to the significance of this research

[1] Bull. 71 U S P H S

The serious prevalence of pulmonary consumption in the trade may be gathered from the fact that the affection is nearly ten times as common among male garment workers as among soldiers in the federal army The garment industries favor the prevalence of pulmonary tuberculosis (*a*) by intensifying bad postural habits, (*b*) possibly by reason of the presence of suspended matter, or what is spoken of as woolen "fly" in the trade, in the air of workshops, and (*c*) by reason of the lower state of metabolism induced by the inactivity of a sedentary occupation and insufficient nutrition consequent on low wages For these reasons, garment makers are prone to tuberculosis, and are especially liable to affections of the respiratory tract A much larger proportion of them than is found in the ordinary population suffer from emphysema of the lungs, chronic bronchitis, and chronic catarrhal conditions of the nasopharynx

As most of these affections have at least some infectious element in them, the recommendations of the Public Health Service for the lessening of the dangers to the community from the garment working trades are worthy of wide consideration They suggest that "fly" should be eliminated from the air of the workshops by suction cleaning, and the coating of the floors with some dust-retaining oil Dry sweeping should be rigidly suppressed If good habits are insisted on at the beginning of work at the trade, better postures are assumed, and the danger from lung compression by stooping is avoided The general health would be much better preserved, and resistive vitality distinctly heightened, by the enforcement of regulations against promiscuous spitting, as well as against the use of the common drinking cup and the common towel In recent years there has been a marked improvement in these matters, but much remains yet to be done, and numerous evasions of the regulations have been noticed in the shops The high prevalence of tuberculosis among garment workers, and their direct relation to the public, make the absolute enforcement of such regulations imperative Finally, the care of the mouth and the teeth represents an extremely important element in prophylaxis, and above all in the preservation of health, so that the investigators rightly insist rather emphatically on including these among their recommendations Such matters seemed more of personal than of public interest only a few years ago, but now their relation to public health becomes very clear

Recent years have brought so much amelioration of the working conditions among this class that there seems every reason to think that only a little more interest is needed now to remove most of the abuses that are responsible for the ill health of the workers With the definite knowledge presented by this investigation, it would be quite possible to make this trade at least no more dangerous than a good many others, and to eliminate most of the risks which now exist of respiratory affections being spread beyond the workroom

LESSONS FROM RECENT CHOLERA OUTBREAKS

The statistics and experiences derived from the cholera outbreak in Manila somewhat more than a year ago furnish a number of new considerations for the guidance of those entrusted with the problems of public health[1] Two important features stand out clearly in the light of the successful control of the situation in the Philippines One of these is the demonstration that in effectively combating a cholera invasion, the use of laboratory facilities in the making of bacteriologic diagnosis on a large scale is absolutely essential Without such assistance as is available in the well-equipped Insular Bureau of Science, the results which have been accomplished would have been impossible From November 1 to November 10 alone approximately 20,000 bacteriologic examinations were made, and before the work of inspection was completed, the number of examinations must have exceeded 100,000 The administration of such a service is, by itself, an affair of no small magnitude, and the task assumes an even more formidable aspect when one recalls that social and political difficulties often need to be overcome in order to make possible an inspection of persons who usually present no outward manifestations of ill health Carriers must be detected regardless of the consequences To avoid a danger one must know where it lurks

Lieut-Col Munson, who was the adviser of the Bureau of Health, but who has now returned to this country, has remarked that the work at Manila meant invasion of the accepted rights of the home and of the individual on a scale perhaps unprecedented for any community The collection of the fecal specimens might fairly be regarded as repulsive to modesty Add to this, he continues, the facts that the search was made among persons, to themselves and others apparently healthy, who could scarcely fall even within the class of suspects, and that those found to be carriers were subjected to all the inconveniences of isolation, separation from family loss of earning capacity, etc , and it is apparent with what tact and caution the work had to be carried out and public opinion created in favor of it as an unpleasant but necessary measure

---

[1] The information cited in this connection is derived from a paper read by Lieut Col E L Munson of the United States Army at the annual meeting of the Philippine Islands Medical Association, Philippine Jour Sc, Sec B, Trop Med 1915, x 1

The second lesson of the Manila outbreak of 1914 was the importance of the cholera carrier In periods when the mortality is high, the proportion of persons who are carriers without presenting symptoms of the disease will be relatively small, but when the mortality is light, according to Munson the lack of virulence in the germ will probably permit it to be harbored in many cases without the production of symptoms, so that a considerable percentage of carriers may be expected Outbreaks such as that of 1914 in Manila accordingly, occur in which the carriers appear to have been not only the most numerous but also the most insidious and dangerous sources of infection It was undoubtedly spread chiefly by personal contact Public water supplies and articles of food—all of which were formerly charged with a major offense in the transmission of such diseases—were eliminated as channels of infection, and likewise the flies played an insignificant part at most in its spread According to the experts in the field,[1] the lack of use of toilet paper, certain habits in the use of the toilet, infected fingers, and the habit of eating food with the hands from a common dish furnish opportunities for passing the infection from the carrier to another person

A further lesson emphasized by the recent experiences is that the five-day period usually accepted for incubation and quarantine will not suffice in a very considerable number of instances This, as Munson points out, sheds light on cholera situations not otherwise readily explained An observed convict who died of true cholera after an eighteen-day period as a carrier "might have traveled half way around the world scattering his infection broadcast" and died of the disease in a place thousands of miles from any other source of infection There is a warning in such cases, says Munson, that health officers all over the world would do well to heed

An examination of many cholera patients and carriers by Schobl[2] showed that vitality of cholera vibrios in the human body is not inconsiderable In forty-three out of eighty patients, the stools were positive for from two to seven days, in twenty-two, from one to two weeks, in six, from two to three weeks, in one case, for forty-eight days Treatment to free the intestine of the invading micro-organism seems to have been of little value Trained experts are necessary to manage the serious situations that may be created Munson's advice deserves to be emphasized the prompt eradication of a general cholera infection includes the detection and isolation of carriers as a scientific prerequisite

FOODS AND DRUGS IN SMALL PACKAGES

There has lately been considerable agitation over the subject of "package food" The questions involved in the sale of edible products in package form are in many ways similar in principle to those related to the distribution of common drugs and chemical preparations in special containers instead of the usual and older method of sale in bulk There are products like canned goods among foods, or therapeutic serums among medicinal articles, which cannot be distributed satisfactorily in bulk because of inherent difficulties in their preparation and preservation These substances must be kept sterile until used, and hence demand a special container But aside from such obvious necessities, the problem of the relative advantages and disadvantages of package goods perhaps deserves to be carefully weighed in these days of increased cost of living Some features of the arguments involved have recently been summarized by Street[1] of the Connecticut Agricultural Experiment Station It is regarded as a favorable feature that the labeled small sealed package gives some assurance respecting the quality of the goods it contains, inasmuch as the manufacturer is usually eager to establish a reputation for them, and therefore finds it to his advantage to furnish a satisfactory product This is doubtless correct in many cases, so that a particular brand of package goods comes to stand for some special merit In certain instances, however, the real value or usefulness of the product is obscured by the advertising features of the special package Attention is directed thereby to incidental properties of the contents, to some color, flavor or alleged quality which has nothing to do with food value, nutritive superiority or therapeutic merit It is the package rather than the product which becomes the attraction to the purchaser, and almost invariably at a charge which must include extraneous costs not suspected by the purchaser It is not unfair, therefore, to ask whether the same price expended on bulk goods by a discriminating purchaser would not, in many cases, secure better values

It must be admitted that the sealed package usually makes for cleanliness and sanitary conditions, that it sometimes conserves flavors and other sorts of dietetic attractiveness, that it tends to "standardize" prices and protect the ignorant purchaser, and that it offers many conveniences for transportation and storage We must nevertheless learn to count the cost of extraneous elegance and attractiveness And when the needs of institutions rather than persons or families are taken into consideration, the disadvantages of many varieties of "loose" foods need to be seriously debated before the latter are condemned "The consumer of limited income," says Street, "has no more economic right to buy crackers, for instance, in small packages than he has to buy champagne, caviar, pâté de foies gras, or a hundred other similar luxuries " Here is a point of view which suggests the desirability of establishing greater skill in marketing among our people as a whole

---

[2] Schobl O Observations Concerning Cholera Carriers Philippine Jour Sc Sec B Trop Med 1915 x 11

[1] Street J P Foods That Are Marketed in Small Packages, Mod. Hosp 1915 v 168

If we object to the purchase of familiar drugs like hexamethylenamin or acetanilid under fancy trade names in expensive form, how shall we defend the comparable practices in the food industries? The question becomes particularly acute in institutional management, where superfluous paper, pasteboard, glass and tin, along with a liberal allowance of printers' ink, can scarcely make good the deficit in real nutriment or medicinal potency Manufacturers of superior brands are beginning to appreciate this, and are meeting the objections by supplying their particular products in larger containers at more economical prices, aiming merely to protect the reputation of their goods by a special label There is a marked distinction between buying a particular brand of, say, boric acid or saccharin, under conditions which identify the maker, and purchasing expensive small packages of the same items with mystical designations

The net weight or volume package laws are intended to give a welcomed and adequate opportunity to every purchaser to ascertain the true content of every package which he pays for It will require considerable education in the reading of labels to make him appreciate that what appears like a half pound of attractively cartoned crackers is in reality only a fraction thereof, or that a large box of breakfast food is liberally filled with an inner container In any event, all the newer requirements for the labeling of foods and drugs in a truthful manner represent steps in the direction of progress The clearer the truth is brought out, the greater will be the advance in the practices concerned

Current Comment

THE EFFECT OF PURIN FOODS ON THE URIC ACID CONTENT OF THE BLOOD

Until quite recently, one of the most helpful indexes of the result of any dietary regimen or therapeutic measure involving metabolism was obtained by an analysis of the urine Thus, the tolerance for carbohydrates was ascertained by examination of the secretion from the kidneys for sugar after the ingestion of varying quantities of this type of foodstuff The relative ability of the kidneys to excrete the usual tissue waste products and inorganic salts was likewise ascertained by urinary analysis, and the efficiency of the renal functions judged on this basis The advent of suitable methods for the analysis of very small quantities of blood—the so-called micro-analysis—has transferred the seat of observation to the circulating fluid in the vascular system Blood analysis for clinical purposes is making rapid strides, not only in the direction of qualitative tests, such as those for evidences of syphilitic and other infections, but also along quantitative lines Several useful "clinical" methods for sugar estimation in blood have been published, and nonprotein nitrogen, urea, creatinin, uric acid, fats and lipoids have been brought within the scope of feasible determination on small samples of blood Enough is already known to demonstrate the value of many of the facts thus ascertained for the clinic of kidney diseases The ingestion of purins, either free as they occur in meats, or in the form of the nucleoproteins of glandular tissues like liver, sweetbread, etc, is followed by a decided increase in the urinary output of uric acid Little has been known regarding the immediate effect of the absorption of purins on the uric acid content of the blood Denis[1] has recently found, from studies at the Massachusetts General Hospital, that in normal individuals no increase in the circulating uric acid is produced by the ingestion of even large quantities of purins It has further been found that the intake of ordinary protein may be increased from an amount sufficient to give from 6 to 8 gm of urea in the twenty-four hour urine to that sufficient to produce a daily urea excretion of from 30 to 50 gm without producing an increase of more than 2 or 3 per cent in the circulating urea As Denis points out, it would thus seem that the normal kidney reacts toward an excess of uric acid in a way essentially similar to that in which it conducts itself toward an excess of urea, and is able to excrete the excess of uric acid presented to it when a diet high in purins is fed, thereby keeping the circulating uric acid at the same level as that obtained when only endogenous uric acid is to be excreted When damage to the kidney has occurred, and even before this has progressed to the point at which nitrogen retention is apparent, as shown by the nonprotein nitrogen values, an accumulation of uric acid takes place in the blood after a short period of purin feeding This is interesting not alone from the evidence that it brings of the importance of the renal efficiency for the level at which uric acid circulates in the blood, but also in its relation to diagnostic procedures Denis suggests that when the determination of uric acid in the blood is undertaken as a diagnostic test, the insistence on a preliminary period during which no purin-containing foods are consumed is unnecessary except in cases in which kidney insufficiency exists, or perhaps in the case of persons who habitually consume extremely large quantities of purin-containing foods

HEMOGLOBINOPHILIC BACTERIA

Although bacteriologists have long been familiar with a rather large group of bacilli which grow artificially only in a medium containing hemoglobin, the peculiarities of these hemoglobinophilic micro-organisms are not so generally known by those who do not specially cultivate this field of study The most conspicuous example of the group is the bacillus definitely recognized by Pfeiffer in 1892 as the etiologic factor in influenza Its discoverer proved the hemoglobinophilic character to be a property of bacteria hitherto unknown The first cultures were made from pus derived from the bronchial secretions of influenza patients It was the failure to secure subcultures on the usual nutrient mediums which directed attention to the part played by the accidentally introduced pus in the successful attempts and led to the observation of the unique role of the blood pigment in connection with these organisms Davis[1] has recently called attention to the further interesting fact that certain of the hemoglobinophilic bacteria identical with or closely related to the influenza bacillus multiply more rapidly when grown on mediums in the presence of other bacteria, such as streptococci or staphylococci Their virulence for animals is also increased This means that they show to a marked degree the property of symbiosis It is a well-known fact that influenzal infection may often aggravate other conditions, and severe mixed infections are not uncommon The influenza bacillus, in particular, does not form spores, and is exceedingly sensitive to all sorts of bactericidal agencies On culture mediums the bacilli die in a short time unless they are transplanted Davis reminds us that the hemoglobinophilic bacteria are interesting in that they are pure parasites, for the very evident reason that only in animals can they find the hemoglobin, which so far as is at present known, is necessary for their existence Inasmuch as they are delicate organisms, their length of life outside of the animal body is very short, not exceeding a few days at most. Davis also recalls that the exact role which hemoglobin plays in the metabolism of these micro-organisms is not known Inasmuch as extremely minute quantities of the blood pigment in mediums suffice for growth it is unlikely that the hemoglobin is necessary because of any purely nutritive properties

---

THE PUBLIC LAUNDRY

If our industrial procedures and household practices remained unchanged from one generation to another, it might become far easier than it has been to control disease and stamp out familiar infections No sooner, however, has one factor been controlled by some scheme of sanitation than changing custom has shifted the incidence of the supposedly eradicated danger and raised a new problem of health control Thus, when laundry work was largely confined to the home, the possibility of infection was limited to a smaller group, and the opportunity for exposure to contagion easily appreciated and provided for Today the handling of soiled clothes is being transferred more and more to special plants in which materials from many homes and still more individuals are brought together where employees come into contact with it The possibility of infection under such conditions must vary for specific diseases, and depends on the probable readiness with which the micro-organisms concerned are transferred by soiled linen, and further on the efficiency of the laundry processes as a mode of sterilization It is doubtless true that some of the more important disease germs are transmitted from individual to individual without any intermediate conveying device, nevertheless there are many infections, such as typhoid fever, venereal diseases, etc, which are known to be transmitted through fomites So long as typhoid fever can be charged to the cook who has handled the food, it is not difficult to conceive of a similar transmission through the laundry worker The high temperature, soap, washing soda and other chemicals to which clothes in the laundry are subjected in the washing process are responsible for a sterilizing action Bacteriologic examinations have repeatedly demonstrated that it is effective Dr Dederer,[1] who represents the Committee on Occupational Diseases of the woman's department of the National Civic Federation, frankly states that there is no danger to public health from "mixed washing" of clothing with contaminated articles It is pointed out, however, that while the washing process practically sterilizes the clothes, the reinfection of clean linen is possible when it is sorted and counted in the same room with soiled linen Clean linen, when exposed to infection through contact with soiled linen, may disseminate infection The upshot of this is that soiled linen ought not to be received, sorted or marked in rooms in which clean linen is kept Eating and drinking should be prohibited in rooms in which soiled linen is manipulated, and laundry workers should be instructed concerning the latent hygienic dangers which they may encounter in their work Sanitary measures involving personal hygiene are essential for their own welfare as well as that of the public served The problems involved have never received any serious attention from public authorities in this country, but the rapid growth of the laundry business is certain to awaken interest in them, as it has been aroused in the case of public restaurants, bakeries, food shops and other institutions which are assuming household functions

THE NECESSITY FOR MORE INTENSIVE STUDY OF PRISONERS

Society itself is made a partner in crime by some of the methods aimed at the prevention of crime That our present undiscriminating system of dealing with offenders against the law too often makes criminals is no news to those who have given it study, but reform is as yet sporadic and tentative Two recent articles emphasize the need of study and classification of prisoners from the point of view of mentality and social adjustment An abstract of one of these, an account of an examination by Drs Ordahl and Singer of convicts at Joliet, appears elsewhere in this issue[2] The other, Dr E R. Spaulding's elaborate study of 500 inmates of the Massachusetts Reformatory for Women,[3] was reviewed in the Current Medical Literature Department, October 23 In both of these, as in other similar studies, the large proportion of mental defectives found among the prisoners is striking Evidently it is unjust to these subnormal persons to punish them as if they were normal and responsible, and just as evidently it is a risk to society to release them at the end of their terms of imprisonment as if they were normal and responsible Spaulding rightly urges the necessity of adequate provision by the state for permanent custodial care of all committable mental defectives, whether or not they have court records

---

[1] Dederer Ebba A. Danger to Laundry Workers of Infection from the Handling of Soiled Linen Am. Jour Pub Health 1915 v 875

[2] An Examination of Prisoners at Joliet Penitentiary Miscellany, The Journal A. M A. this issue p 2189

[3] Spaulding E. R. Our Criminal Problem from the Standpoint of Classification and Segregation Boston Med. and Surg Jour 1915 clxxiii No 15 abstr The Journal A. M A Oct. 23 1915 p 1487

Spaulding's article and that of Ordahl and Singer both emphasize the need of separating the more hopeful and educable class of prisoners from the class of confirmed and incorrigible criminals Both articles also lay stress on the value—indeed, the necessity—of the indeterminate sentence Although this phase of the matter is not discussed in either article, the data in both likewise suggest the reason for the undeserved odium, which has in some instances been thrown on the workings of the indeterminate sentence and other excellent measures The trouble with methods requiring discrimination and wisdom in their application is that they presuppose the possession of exact knowledge with regard to the prisoner, and this exact knowledge too often is not available, for the prisoner has not been sufficiently studied Ordahl and Singer emphasize the "scanty and very unsatisfactory" character of the information on the subject of convicts available for the use of the board of pardons Thus the dangerous criminal may be released to the detriment of society, and the pliable but not as yet dangerous accidental offender may be retained to his own detriment Knowledge is needed, and with increased knowledge the more advanced methods will become feasible

THE QUESTION OF BACILLEMIA IN TUBERCULOSIS

The pathologic condition now familiarly known as bacteremia, in which the micro-organisms of disease are not merely local in their distribution but are generalized by being carried about in the blood stream, is in any event a grave one The capacity of bacteria to invade the circulation seems to be more common than was formerly believed to be the case Thus the organisms of typhoid fever are now known to circulate freely in the blood during the first two weeks of the disease and often longer than this Lobar pneumonia may be accompanied during its acute stages by a pneumococcus septicemia Organisms like the streptococci and the anthrax bacilli give rise preeminently to the septicemic forms of infection If they multiply rapidly in the blood, the situation immediately becomes serious
of vary ther cases micro-organisms obtain temporary
relative into the blood current and either find lodg-
tissue waste some tissue, as on the valves of the heart,
wise ascertained by some immunizing agency and dis-
of the renal fe circulation An accurate knowledge
advent of suital deportment of each variety of micro-
small quantities oly affords an important basis for
—has transferred phylactic procedures The evidence
lating fluid in the value of tubercle bacilli in the blood
clinical purposes is ns is exceedingly conflicting[1] No
the direction of qualita
dences of syphilitic and one will deny that the micro-organisms occasionally enter the blood The distribution of tuberculous lesions is of itself suggestive on this point This, however, does not settle the question as to what extent and in what respect acute miliary tuberculosis is a generalized infection Kessel[2] has lately made new attempts to grow tubercle bacilli directly from the blood, and to demonstrate their presence by direct microscopic examination and particularly by careful direct inoculation of susceptible animals with the blood from patients with advanced pulmonary tuberculosis — all with negative results Kessel admits that this outcome in the forty-seven cases examined by him does not prove conclusively that tubercle bacilli are never present in the circulation, but they strongly suggest that a bacillemia such as is present in other infectious diseases is at least uncommon in pulmonary tuberculosis even in advanced stages of the disease It may be that from time to time tubercle bacilli are washed into the circulation from a pulmonary focus, but it is shown by experimental evidence from the effect of direct intravenous inoculation that in such an event they rapidly disappear from the blood

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest, such as relate to society activities, new hospitals, education, public health, etc)

ILLINOIS

Smallpox at Alma—It was reported from Alma, December 3, that thirty-two cases of smallpox have been diagnosed in the town

Batavia in Quarantine—The town of Batavia is practically quarantined because of a diphtheria epidemic All churches and schools have been closed and all persons less than 19 years of age have been ordered to remain in their own homes whether they have the disease or not

Medical Library Moved—The medical department of LaSalle City Library has recently been moved to the Hygiene Institute, LaSalle, and is now known as the LaSalle-Peru Medical Library The library has at present 703 bound volumes and about 100 unbound periodicals

Quarantine Lifted—All of Cook County with the exception of the Union Stock Yards and two infected areas in Lyons was ordered released from foot and mouth disease quarantine, December 10 In Lake County, Shields Township alone remains restricted, in McDowell County many townships remain free areas and all of Du Page County is declared free with the exception of the territory in Downers Grove Township within 3 miles radius of infected areas in Lyons township, Cook County

Northern Central Physicians Elect—At the forty-second annual meeting of the Northern Central Illinois Medical Association held in Peoria, December 8, Dr James A Marshall, Pontiac, was elected president, Dr Frederick W Wilcox, Minonk, first vice president, Dr David S Conley, *Streator, second vice president*, and Dr George A Dicus, Streator, was reelected secretary-treasurer Two of the oldest medical men in the state, Drs William O Ensign, Rutland, and James Tweddale, Washburn, were present at the meeting

Personal—Dr Victor A Bles, a member of the staff of the Elgin State Hospital, is seriously ill as the result of a pulmonary hemorrhage Dr Bles has received notice of his appointment as clinical assistant in the department of neurology and psychiatry in the University of Illinois——Dr Frederick W Werner has been elected chairman of the

LOUISIANA

Decision Under Fraudulent Advertising Act.—Dr Oscar Dowling, New Orleans, executive officer of the Louisiana State Board of Health, writes that on December 11 an important decision in favor of the board was rendered by Judge Ott under the Louisiana Fraudulent Advertising Act Two weeks before, the board had preferred charges against C J Allen and W M Chapman, who were advertising "Herbs of Life," manufactured by the Herbs of Life Medicine Company, Springfield, Ill , and F D Haaze, who was exploiting the merits of "Shaker Tonic," "Shaker Oil" and "Shaker Balm Soap" manufactured by the Life Tone Medical Association of Memphis, Tenn The first two pleaded guilty and were fined $100 and costs, the fine being remitted on their agreement to leave the state for good The third defendant was tried December 11 He was found guilty and fined $325 He says the case will be appealed to the supreme court on the ground of unconstitutionality of the law

MARYLAND

School Closed by Diphtheria.—The Williamsburg School has been closed for the second time this term on account of the appearance of several new cases of diphtheria

Tuberculosis Week.—The past week was devoted to a warfare on tuberculosis in Baltimore to impress on the people of the city the importance of taking an active part in the campaign against the disease. Each day was set aside for some particular educational demonstration showing the ravages made by the disease. The program was confined to three days

Chinese Physicians' Visit.—Two women physicians from China arrived in Baltimore recently and visited the Johns Hopkins Hospital, where they will study the work done by the institution and the lines on which it is managed They are Dr Adela E Sheffer and Dr Wynao S Wango of Shanghai, China, who came to this country with seven other physicians to make a study of the hospitals in America

Medical Survey—The first medical survey to be started in Maryland was inaugurated in Frederick County, November 29, with an inspection of the Johnsville School The survey is being made by Surgs Talliaferro, George L Collins and Ed H Mullan of the United States Public Health Service, and Drs Richard B Norment and Joseph Brown of the State Board of Health

Gift to the Johns Hopkins—A valuable collection of periodicals, monographs, and other medical books, consisting of more than 4,000 volumes, was presented to the Johns Hopkins Hospital by Dr Howard A Kelly, Baltimore The collection can be said to be the life study of Dr Kelly for most of the books deal with his own special work in gynecology and obstetrics and are valued at about $25,000 It is planned in the near future to have a suitable building erected for the library

Personal—Dr William H Welch, professor of pathology of the Johns Hopkins Medical School, who has been in China during the summer with Dr Simon Flexner of the Rockefeller Institute, devising a way to introduce modern medical methods in the empire, will sail December 18 from Yokohama, Japan, for this country On the return of Dr Welch to Baltimore, the General Education Board will hold a meeting to discuss the addition of a new department to the Johns Hopkins Medical School and Hospital——Dr Marshall B West, health officer of Catonsville, who was operated on several weeks ago at the Maryland University Hospital for appendicitis, has returned to his home and is improving rapidly——Dr Charles F Nolen, Baltimore, who was recently operated on at the Union Protestant Infirmary, has recovered and resumed practice

NEVADA

Correction—Dr Martin A Robison advises under date of December 7 that the item in The Journal of December 4, stating that he and Dr Henry Bergstein had resigned from the Reno Board of Health is not authentic, that both these gentlemen are serving on the board and have been serving since their appointment

NEW YORK

Half a Million More Needed—The creation of a division for the prevention of tuberculosis in connection with the State Health Department, the expense of laboratory work and the payment of the full salary of $3,000 a year to sanitary engineers are the three principal reasons for the increase in the appropriation in health work sought by State Commissioner of Health Biggs

New Officers—At the annual meeting of the Queens-Nassau Medical Society held in Long Island City, November 30, Dr Edward H Pershing, Woodmere, was elected president, Dr John J Kindred, Long Island City, vice president, and Dr James S Cooley, Mineola, was reelected secretary-treasurer of the society for the twenty-seventh consecutive term

New York Physicians to be Prosecuted—The New York *Sun* of December 10 announces in a telegram from Albany that prosecution of 300 physicians for violation of the vital statistics law has been ordered by the State Department of Health The offense in every case was the violation of the section requiring the registration of births within five days Dr Cressy L Wilbur, director of the division of vital statistics, states that physicians will be given an opportunity to explain the delay, but that only substantial reasons will be allowed as excuse for violation of the law

Sanatorium Notes—A proposition for the construction of a tuberculosis hospital, to take the place of the institution recently burned at Elmira, has been taken up with the Elmira Tuberculosis Hospital Sanatorium Commission The plan is to make a bond issue of $2,000 in every budget when the 1915 budget has been adopted and to continue this same amount in the budget each year until the $12,000 deemed necessary for the erection of the hospital has been paid——A special committee has been appointed by the board of supervisors to serve for a month in an advisory capacity regarding the Steuben County Tuberculosis Hospital for which an appropriation of $30,000 was authorized at the recent election

New York City

Neurologists Elect—At the annual meeting of the Brooklyn Neurological Society, Dr Siegfried Block was elected president, Dr Charles P Frischbier, vice president, and Dr John F W Meagher, secretary-treasurer, and Dr James F Morrison, librarian

Measles Among Belgian Refugees—Three hundred Belgian refugees were landed here on December 8 and taken to Ellis Island for examination Forty of the children were found suffering from measles and with their mothers were detained at the hospital on Ellis Island All but 110 of the number have been held for further observation

Personal—Dr George A Wyeth was the delegate of the Bronx Board of Trade to the Rivers and Harbors Convention held in Washington, D C, December 8——Dr Joseph J O'Connell, health officer of the port of New York, Brooklyn, is reported to be seriously ill with heart disease at his official home, Quarantine Station, Staten Island

Course of Instruction for Food Inspectors—A course of lectures, conferences and demonstrations dealing with the various aspects of pure food work has been arranged by Mr Lucius P Brown, director of the health department's bureau of foods and drugs The lectures are in the nature of a postgraduate course and are planned so as to perfect inspectors in the details of the various branches of their work

Tuberculosis in New York—A statemen issued by the department of health in connection with the work of tuberculosis week places the number of persons afflicted with tuberculosis in this city at 50,000 Of the 37,000 known to the board of health only 3,200 are registered under the care of private physicians and 6,000 under the care of city institutions It is estimated that 15,000 are treated at clinics

Intern Examination—A joint examining board will hold a competitive examination of candidates for internship in the New York, Roosevelt, St Luke's and Knickerbocker hospitals on a day not yet selected Application blanks and full information may be obtained from Dr Charles L Gibson, chairman of the Joint Hospital Examining Board, care New York Hospital, 8 West Sixteenth Street, New York City Applications properly filled out must be in the hands of the committee on or before December 31

Woman's Hospital Opens New Wing—The Thompson Pathological Building which forms the west wing of the Woman's Hospital was formally opened on December 9 as a feature of the sixtieth anniversary of the hospital This structure was erected at a cost of $150,000 and is the gift of Mrs Frederick F Thompson An address was delivered by Dr Henry Clarke Coe and Dr Wilfred T Grenfell of Labrador was one of the speakers During the past year 2,500 patients have been treated in the hospital and 3,728 operations have been performed

College of Physicians and Surgeons Formally Named—The name "College of Physicians and Surgeons of Columbia University" has been adopted officially and the school formally declared to be the medical department of the university It has been considered such for years but this formality has never been gone through At this same meeting of the trustees the committee on conference was authorized to continue negotiations with the Presbyterian Hospital and to cooperate with other hospitals and institutions with the ultimate purpose of establishing a great medical center on the lines already planned

Medical Society Topics—Dr Arthur B Duel delivered an address before the New York Academy of Medicine, December 16, on "Orientation and Equilibration, A Study in the Sense of Position and Movement, Its Dependence on the Vestibular Apparatus and Its Importance in the Whole Field of Medicine"——The fourth lecture of the Harvey Society series given at the Academy of Medicine, December 18, by Prof Florence W Sabin of Johns Hopkins University, is on the subject "The Method of Growth of the Lymphatic System"——The first meeting of the New York Geriatric Society, which was organized in June last, was held December 15, at which the subject for discussion was "The Neglect of the Aged"

Surgical and Medical Clinics in New York City—The Society for the Advancement of Clinical Study announces a continuation of its bureau of information relative to surgical and medical clinics to be held in New York City A bulletin board is maintained for this purpose at the Academy of Medicine, 17 West Forty-Third Street, in charge of a competent attendant who is on duty from 9 to 12 a m and from 2 to 6 p m The clinics are posted on a special circular of information which is mailed to outsiders at a cost of 50 cents per week The bulletin board contains the daily clinics as well as those stated at various hours at different hospitals Facilities are thus afforded to visiting physicians to observe special operators or clinicians

Another Building for Mount Sinai Hospital—Plans have been prepared for a new building for the mount Sinai group This is to be known as the Guggenheim Memorial, and the entire expense of its construction will be defrayed by the six Guggenheim brothers The estimated cost of the new building is $500,000 It will follow the design of the general construction of the main building fronting on Fifth Avenue and will be a complete hospital in itself It will also have a separate staff of doctors In addition to this gift Mount Sinai Hospital has received $50,000 from Murry Guggenheim and $5 000 from each of his brothers to carry on the work of completing and equipping the five other buildings now in the course of construction

Queensborough Hospital for Contagious Diseases—Hitherto cases of contagious diseases occurring in the Borough of Queens and requiring hospital care have been taken to Kingston Avenue Hospital in the Borough of Brooklyn, but it is now announced that the new Queensborough Hospital will be complete and ready to receive patients on Jan 1, 1916 The hospital is located on a farm between Jamaica and Bayside It is of mission type, three stories high and thoroughly equipped for the purposes for which it is to serve The wards are divided into cubicles so that there will not be more than two beds in each cubicle, thus insuring almost perfect isolation The hospital contains 20,879 square feet of floor space and 243 800 cubic feet of room and is so designed that a large number of cases can be cared for at a small expense

"Patent Medicine" Interests Would Defend Themselves—A report of the recent meeting of the New York Pharmaceutical Conference as published in the *N A R D Journal* mentions an offer from an unnamed source of legal and financial aid for druggists of this city who are prosecuted by the health department authorities for alleged violations of this ordinance ' The proposal for accepting this aid was placed before the representatives of the conference by Dr William C Anderson, the chairman of that body, who refused to make public the name or names of those from whom the offer came The Pharmaceutical Society as a whole passed resolutions which have been quite widely published, signifying their intention of upholding and cooperating with the regulations of the department of health with reference to patent medicines"

Whooping Cough Clinic—The November *Bulletin of the New York City Department of Health* gives a full report of the first year's work of the whooping cough clinic which it has been conducting The total number of cases treated at this clinic during its first year was 1,397 It was intended at first to treat only patients in the clinic district but it became necessary to let down the barriers in face of the numbers clamoring for treatment The method of treatment followed consists in giving three to four subcutaneous injections of vaccines, one every other day, after which for a period of three or four days a mixture of antipyrin and codliver oil is used for a period of three or four days The whooping cough usually disappears after the third or fourth injection Those familiar with the work of this clinic find that it fills a long felt want irrespective of the therapeutics employed, and that at least two more such clinics should be established, one in the Bronx and one in East New York

Use of Diphtheria Antitoxin.—For many years the department of health has been furnishing diphtheria antitoxin free of charge to the public and a corps of physicians was maintained to inject the antitoxin on request Two years ago the administration by the department's physicians was discontinued but additional facilities were provided for the prompt and ready use of this remedy by private physicians The statistics of the health department show that there was more antitoxin sold in 1914 than in 1913, but that there was a very material reduction in the amount distributed free in 1914, with a very appreciable increase in the number of cases of diphtheria reported This falling off in the use of free antitoxin was chiefly confined to Manhattan and Brooklyn with an increase in the number of cases of diphtheria in both boroughs, and in a measure accounts for the increased incidence The department of health calls attention to the great significance of these facts and emphasizes the importance of the universal use of antitoxin in diphtheria

NORTH CAROLINA

Communicable Diseases—An epidemic of scarlet fever in Marion has rendered it necessary to close the public schools, to suspend the Sunday schools and to warn children to stay off the streets and avoid public gatherings

State School Celebrates Anniversary—On November 4, the seventieth anniversary exercises of the State School for the Blind, Raleigh, were celebrated Governor Craig presided, and addresses were made by Superintendent John F Bledsoe of the Maryland School for the Blind, and others

Memorial to Living Physician—The people of Currituck County have raised a fund in honor of Dr William T Griggs of Poplar Branch Of this fund, $150 has been used to purchase an operating table in the Elizabeth City Hospital, and the remainder has been given to the charity fund of the institution

Hospital Notes—The Hendersonville Hospital Association recently elected Dr William R Kirk chief of staff and Drs William B W Howe, Jr, James S Brown, Guy E Dixon, Benjamin F Cliff Andrew B Drafts, James F Cranford and Eugene P Mallett as associates Dr James F Cranford was elected dean of the training school

City to be Sued—The State Board of Health has authorized that action be instituted in the courts to compel the city of Louisburg to install a sewage purification plant, as ordered by the State Board of Health some time ago At present the sewage of Louisburg is discharged into a stream which later supplies other towns in the state with water, and these towns have been compelled to install purification plants to care for their town and to care for other towns still farther down the river

Personal.—Dr Harry Q Alexander, Matthews, Mecklenburg County, was recently elected president of the North Carolina State Farmers' Union for the ninth successive term, and Dr James M Templeton, Cary, was elected vice president ——Dr William W Stancell, assistant physician to the State Hospital for the Insane, Raleigh, is taking postgraduate work in New York, and will move to Montana next year—— Dr and Mrs James L Egerton, Hendersonville, have returned after a six weeks' trip to the Pacific Coast——Dr John H Mease Canton, who has been under treatment in a hospital in Baltimore, has returned and resumed practice—— Dr Hubert B Haywood, Jr, Raleigh, has been elected physician to the New York State Agricultural and Mechanical College, as the result of a competitive examination

Medical Society News—The entire membership of the Buncombe County Medical Society was entertained at dinner by Dr Eugene B Glenn, the president, at his home in Asheville, December 6——The Lincoln and Catawba medical societies held a joint session at Lincolnton, December 6, and were entertained at dinner by the physicians of Lincolnton ——The Pasquetank-Camden-Dare County Medical Society held its annual meeting and election in Elizabeth City, December 1, and elected the following officers president, Dr Wm A Hoggard, Woodville, vice president, Dr John B Griggs, Elizabeth City, and secretary-treasurer, Dr William A .Peters, Elizabeth City——The New Hanover County Medical Society has enlarged its scope and now allows public health workers, dentists and pharmacists to become associate members

PENNSYLVANIA

Personal.—Dr Harry B Rushton has been appointed meat and milk inspector of Reading——Dr Nelson E Newbury, Scranton, was assaulted by the half-crazed son of a patient, and severely beaten

Medical Club Election.—At the annual meeting of the Oil City Medical Club, December 2, Dr Harry H Lamb was elected president, Dr Irwin H Boyd, vice president, and Dr Sylvester W Sellow, secretary-treasurer

Improvement to Hospital—Grand View Hospital, Sellersville, plans enlargements, at its present location, between Sellersville, Menlo Park and Perkasie. Messrs C N and B F Cressmann of Philadelphia are to be its almoners

Guests of Honor—Dr Barton K. Thomas Philadelphia, was the guest of honor at a dinner given to the physicians of Pottstown by Dr T Edmund Mills, December 1——Dr William L Rodman, President of the American Medical

Association, was the guest of honor at a dinner given by Dr John B McAllister at the Harrisburg Club, December 3, and afterward delivered an address at the twentieth anniversary meeting of the Harrisburg Academy of Medicine

Schools Closed on Account of Disease—The borough schools of Robisonia have been closed on account of the presence of diphtheria——The public schools and Sunday schools at Orwigsburg have been closed and children under 16 have been prohibited from attending public gatherings, moving picture shows, etc, on account of a measles epidemic At present seventy-three cases have been reported——Jessup and Marshwood have ordered all schools closed and have prohibited all religious and public meetings for the time being on account of the prevalence of smallpox

Typhoid Infection Traced—State Health Board officials, directed by Dr Samuel Dixon, have been cooperating with the authorities of Abington Township in an effort to trace a number of cases of typhoid fever which have broken out in Abington and Moreland townships, north of Philadelphia According to Dr Dixon there are twenty-two cases and at the time of the first outbreak of typhoid some time ago, it was determined that the cases were distributed along routes served with milk from one dairy Tests were made, not only of milk, but of the water supply, and of oysters, celery, and other raw vegetables The department found everything blameless excepting the milk Improvements have been made at the dairy in question, and a repetition of the outbreak is not at all probable

Philadelphia

Health Bulletins—Big posters, in red ink, to teach mothers how to buy food that will keep their children in good health, will be distributed in a few days by the Child Federation The poster is the fifth bulletin issued by the federation

Rescue Drug Addicts—Drs Horatio C Wood, Jr, and John W Ryan, members of a commission of physicians and business men of Philadelphia, recently formed for the purpose of aiding the habitual users of drugs, sent eleven drug addicts to hospitals, December 3 The expenses for the treatment are paid from a fund raised by the committee from contributions by business and professional men of the city

Inspection of House of Correction—The consulting board recently named by Director of Public Safety Dripps for the aid of persons in the house of correction is composed of Drs James W Anders, Ella B Everett, J Leslie David, Charles H Frazier, Elijah H Siter, Thomas H Fenton, T H Weisenburg, Horace Philips and Frank Crozier Knowles The committee began its work December 15, with a thorough inspection of the Holmesburg institution

Testimonial Dinners—The members of the Samaritan Hospital Medical Society gave a testimonial dinner, December 16, to Dr George Morton Illman at the Mercantile Club, December 16——Prof Jacques Loeb delivered an address on "Adaptation" at the meeting of the Philadelphia County Medical Society, December 8, followed by a reception and supper The meeting was arranged by the committee of the medical society on cooperating allied agencies and institutions

Fatality Record—Despite safety-first campaigns to reduce motor-car accidents, statistics compiled by the coroner show that the year drawing to a close will reach the high-water mark in deaths of this kind Seventy-one persons have met death to date in motor accidents, an increase of fourteen over 1914 However, deaths from trolley accidents have shown a marked decrease, forty-three persons having been killed so far, against fifty-seven last year This number is the smallest since 1906 Railroad deaths total to date about seventy-one, against the same number in 1914

Personal.—Dr Malcolm Grow has been appointed chief surgeon to the twenty-first flying column of the Russian Red Cross——Dr Charles B Penrose has been appointed a member of the Fairmount Park Commission——Dr Wilmer Krusen is said to have been selected by the mayor-elect as director of health and charities——Dr C F Mitchell sailed for France, December 4, where he will serve on the staff of the American Ambulance Hospital——Dr Daniel J McCarthy, member of the University of Pennsylvania *unit* at the American Ambulance Hospital, Paris, has returned from abroad

Tuberculosis Week—The observance of "Tuberculosis Week," which began December 6, was given a flying start in this city A campaign of publicity to arouse this country for a fight against this deadly disease was the object of the crusade At the local headquarters of the National Association for the Study and Prevention of Tuberculosis, 1701 Chestnut Street, hundreds of pamphlets showing the effect of tuberculosis on the human body were distributed Statistics showing the relative growth of the disease in the various states were also displayed This year's program includes a "medical examination day," which took place December 8, when the need for a physical examination for every one was urged

Charities Bureau—Having installed all machinery necessary for undertaking relief work among charitable institutions of the city, the Charities Bureau of the Chamber of Commerce have turned the first wheel in their campaign to supplant indiscriminate giving with scientific methods, the purpose of which is to give 90 cents out of every dollar directly to the cause or persons involved The bureau planned to begin a thorough investigation of all hospitals and institutions doing charitable work The list will cover virtually every hospital in the city In spite of the fact that a number of them are supported through state aid, almost without exception, it was said at the Chamber of Commerce they receive private help, too The examination by the Charities Bureau will take in the organization of these institutions, the administrative methods, the officers and directors Finances will be scrutinized to find out whether the best results are being gained This work will be done through personal visits and the findings placed before the committee, who will pass on the standard of work done and the degree of efficiency shown Members of the Chamber of Commerce will be posted as to what the hospitals are doing in charitable work and a complete list of worthy institutions will be made in order to prevent solicitors of unworthy causes gaining a hearing

WISCONSIN

Mix in Oshkosh—Dr Charles L Mix, Chicago, was the guest of honor and delivered the address at a banquet and joint meeting of the Winnebago County Medical Society and Oshkosh Medical Club, November 24

More Sterilizations Planned—Operations on fifteen additional patients under the sterilization law will be made before Christmas holidays According to a statement of the officials of the State Board of Control, the first ten operations are said to have been entirely successful

Communicable Diseases—On November 29 it was reported that there were twenty-five cases of smallpox at Plymouth ——An epidemic of diphtheria has been reported to be in Block Brook, and on the advice of the deputy state health officer, District School No 4 has been closed Seventeen of the pupils of this school were either ill or there was diphtheria in their families——Antigo reports the presence of thirty-seven cases of smallpox

Sanatorium Notes—A petition has been presented to the Waukesha County Board setting forth the need of a tuberculosis sanatorium and asking for an appropriation for its erection and maintenance——The city council of Milwaukee has voted to rebuild the Blue Mound Sanatorium for the treatment of incipient tuberculosis, Wauwatosa The new institution will accommodate not less than 150 patients Health Commissioner Ruhland also recommends enlarged dispensary service for early diagnosis of the disease——Grant County has voted against the establishment of a tuberculosis sanatorium by a vote of thirty to twenty-three

State Sanatorium Controversy—Dr Norman F Hoffman, superintendent of the State Sanatorium, Wales, whose resignation has been demanded, appeared before the Wisconsin Board of Control at Madison, November 30, and stated that the charges of incompetency against him were unfounded A committee of six Milwaukee physicians who made an investigation of the institution, November 26, reports no dissatisfaction of the management on the part of the patients or employees, that the records of the sanatorium show very favorable results so far as the treatment of patients is concerned, and that the expenses of conducting the institution have been reduced

Rules Against Physician—The attorney general on November 27 advised the district attorney at Antigo that a physician who attends a dependent sick person cannot lawfully charge the town, village or city in which the sick person resides for such service without the consent of the municipality The case in point was that of two physicians who attended a sick woman in Langlade County They performed an operation to save her life and the patient's condition was so urgent that the physicians did not have time to consult the town authorities The town refused to pay the bill and the physicians threatened to bring suit to collect, but the attorney general rules that under the circumstances the plaintiffs have no lawful claim against the town or county

Hospital News—The new hospital building of the Milwaukee Infants' Home and Hospital is nearing completion The building is fireproof, two stories and basement in height and will accommodate about fifty patients This will more than double the capacity of the institution——A hospital has been opened in Bloomer, which will be open to all local physicians——A new Lutheran Hospital is to be erected at Plymouth to cost $40,000 Of this amount, subscriptions of $10,000 have already been received——The county board of Waukesha County has recommended the erection and maintenance of an isolation hospital on the county farm grounds north of Waukesha——Steps have been taken for the formation of a corporation to build a Lutheran Hospital in Superior

Personal.—Dr Moses J White, who has been superintendent of the Milwaukee County Hospital for the Insane, Wauwatosa, for twenty-two years, has been succeeded by Dr Albert F Young, Milwaukee——Dr Frank J Schultz, Milwaukee, has been reelected superintendent of the Milwaukee County Hospital——Dr William F Beutler has been reelected superintendent of the Milwaukee County Asylum for the Chronic Insane, Wauwatosa——Dr John T Corr, Racine, has been elected physician for the blind in the eastern district of Racine County, and Dr William A Fulton, Burlington, to fill a similar position in the western district——Dr Arthur J Patek, Milwaukee, was operated on for appendicitis in Mt. Sinai Hospital Milwaukee November 12, and is doing well——Dr Clyde W Morter, Milwaukee, is suffering from septicemia and is under treatment in Mt. Sinai Hospital

CANADA

Laval's Offer Accepted—A cable has been received from the war office by the Canadian minister of militia accepting the offer of a hospital from Laval University, Montreal It will be established in England as a general military hospital

Queen's University to Get Legacy—The executors of the estate of the late Lord Strathcona have notified Queen's University, Kingston, that the $100,000 left to that university is now available and ready to be paid over to the beneficiaries

Personal.—Dr John M Adams, formerly of Seattle, has arrived at Shornecliffe Kent, to take up his duties wtih the Canadian Army Medical Corps attached to the Forty-Third Winnipeg Regiment, of which Sir William Osler's brother is lieutenant-colonel, and Ralph Conner, the author, is chaplain——Col George G Nasmith, R.A.M.C., Toronto, who has been in charge of the Canadian Field Expedition since the outbreak of the war, has returned for a short rest and then, it is said, will recruit a large medical contingent to return with him to the war zone

Outdoor Expansion at the Toronto General Hospital.—The board of governors of the Toronto General Hospital, acting on the advice of the superintendent, Dr Charles K Clarke, are establishing two new free clinics The first will be for the treatment of contact cases of tuberculosis this may be opened nightly The second will be for social diseases The third will be for occupational diseases, as now that much ammunition is being made in Toronto, there have been increased cases of lead poisoning and other occupational diseases It is expected the establishment of the first two will deal a blow to quack doctors and worthless medicines

Toronto University Hospital Kept Moving—It is understood that the University of Toronto Base Hospital is now located in Macedonia, although some fear is entertained for the rather dangerous position of this hospital Several cables from Toronto to the officer commanding recently have remained unanswered, and the latest word is from a letter from Dr William J O Malloch Writing from Saloniki, Dr Malloch states that it is no wonder residents of Macedonia once called for the apostle St Paul They really needed the whole twelve For a time the unit was divided, some going with some 500 wounded to Malta, but it is understood that the unit has again been reunited

GENERAL

Correction.—In Table 1, p 2142, this issue, the minus-plus sign should be a minus, and in all the tables in the article the minus sign indicates "no trypanosomes"

Porto Rico Physicians Meet.—The annual meeting of the Medical Association of Porto Rico was held in the Young Men's Christian Association rooms, San Juan, P R., December 11 and 12, under the presidency of Dr Pedro Gutierrez Igarravidez

Biologists to Meet.—The Federation of American Societies for Experimental Biology, formed by the Physiological Society, The Society of Biological Chemists, The Pharmacological Society and The Society for Experimental Pathology, will hold its annual sessions in Boston at the Harvard Medical School, December 27 to 29, inclusive

Salvarsan to be Generally Available at Usual Price—We understand that the French and British governments have acceded to the request of the United States government and will allow a six months' supply of salvarsan and neosalvarsan, covering the requirements of the United States, to be shipped from Rotterdam The British consul general at that port has been instructed to issue permits on application for such quantities Farbwerke-Hoechst Co, the American agents, announce that as soon as shipments arrive they will be released to physicians and hospitals as heretofore, and that there will be no increase in price. It is also announced that the patentees are arranging to manufacture the products in this country, but it will take some months before a successful product can be turned out here

Pan-American Scientific Congress—The second Pan-American Scientific Congress will be held in Washington, D C, Dec 27, 1915, to Jan 8, 1916 The congress interests educators, scientists and publicists and its work will be done in nine sections, namely, anthropology, astronomy, meteorology and seismology, conservation of natural resources, agriculture, irrigation and forestry, education, engineering, international law, public law and jurisprudence, mining and metallurgy, economic geology and applied chemistry, public health and medical science, and transportation, commerce, finance and taxation There will also be forty-five subsections The section on public health and medical science will be presided over by Maj Gen William C. Gorgas, Surgeon-General, U S Army The organization headquarters will be the Pan-American Union and the headquarters during the congress will be the New Willard Hotel

Arsenobenzol (Salvarsan) Made in This Country—From a communication received from Dr Jay F Schamberg, director of the Department of Dermatological Research, we abstract the following

The dermatological laboratories of the Philadelphia Polyclinic have been engaged for over three years in certain scientific investigations related to dermatology Over $50,000 have been expended during this time, the financial support coming from a generous citizen of Philadelphia It is not known, however, how long this support will continue. During the past year and a half the laboratory has devoted a considerable part of its activities to chemotherapeutic studies The toxicity of various preparations of mercury have been investigated and efforts made to produce a mercurial compound of greater efficacy than those already in use. A number of new organic mercurial preparations were made in the laboratory and tested out on animals infected with experimental trypanosomiasis This work not being immediately fruitful, the problem was temporarily laid aside and work was begun on arsenical compounds Incidental to this work, salvarsan was reproduced and a number of allied arsenobenzol products made and tested out. In view of the shortage of salvarsan resulting from the war, it was decided to make and distribute salvarsan under its chemical name of arsenobenzol [The name arsenobenzol, by right of priority, belongs to the compound $C_6H_5.As$ As C_6H_5. While this term is also used as a synonym for salvarsan, arsenphenolamin hydrochlorid is more descriptive and a more scientific designation for the drug The latter is the name adopted by the Council on Pharmacy and Chemistry, and is in New and Nonofficial Remedies It would seem that arsenobenzol is too firmly established in chemical literature to be ignored and, further, it is not a correct description of the compound known as salvarsan—Ed] The director of the laboratories had a conference with the New York representative of the Farbwerke Hoechst and informed him that in the interests of humanity and the public health, the laboratories had determined to supply arsenobenzol to physicians and hospitals having urgent need for the same During the course of this conversation is was a feeling of both parties to the interview that no court of equity would issue an injunction against the manufacture and distribution of a drug that was saving life and conserving the public health at a time when such drug could not be supplied by the patentees It is stated that the arsenobenzol made by the dermatological laboratories has now been employed on hundreds of cases with excellent therapeutic results, and with no report of any accidents or untoward complications The drug is slightly less soluble than the German product and the solution requires to be filtered It is prepared otherwise in the same manner as salvarsan and must be neutralized by the addition of sodium hydroxid solution The toxicity tests on animals and the therapeutic tests in rats infected with experimental trypanosomiasis give substantially the same results as those obtained from the Ehrlich product The dermatological research laboratories will distribute the drug at the antebellum figure of $3 00 per tube for ampoules containing 0 6 gm and $2 50 per tube for ampoules containing 0 4 gm In order that the drug may be supplied to as many hospital patients as possible, it has been decided to distribute the arsenobenzol to hospitals at the rate of $2 00 for the 0 6 ampoule and $1 50 for the 0 4 ampoule, with the understanding that such drug is to be used only on ward and dispensary patients It was the desire of those connected with the laboratory further to reduce the price of the drug to hospitals, but legal advice to the effect that such reduction might ultimately injure the market of the patentees, has for the present restrained such action The pledge is given that any profits that may accrue from the sale of this drug shall be exclusively devoted to the establishment of a fund for further scientific research and no part thereof shall inure to the benefit of any individual The chemical work is carried out under the supervision of Dr G W Raiziss and the pathologic work under Dr John A Kolmer

WAR NOTES

Appreciation of Red Cross—A letter has been received at American Red Cross headquarters from Count Talleyrand-Perigord who is assigned by the German Red Cross to look after the welfare of the Americans and cooperate with them in their relief work among the wounded at Gleiwitz and Kosel, in which he pays eloquent tribute to the skill and efficiency, devotion and self sacrifice of the personnel of the American Red Cross units——The empress of Russia has conveyed to the American Red Cross Society sincere expressions of her gratitude for the gifts to the Russian Red Cross and the assistance the American Red Cross Society has given the sick and wounded——Queen Eleanore of Bulgaria has cabled to the American Red Cross expressing her heartfelt gratitude for the succor furnished to the Bulgarian sick and wounded by the Red Cross

Aid for Belgian Physicians—The report of the treasurer of the committee of American physicians for the aid of the Belgian profession, for the week ended December 11, lists the following contributions

Buffalo Medical and Surgical League, Buffalo, N Y		$ 5 00
Washington County Medical Society, Calais, Me		25 00
Receipts for the week ending December 11		$ 30 00
Previously reported receipts		7,873 84
Total receipts		$7,903 84
Previously reported disbursements		
1,625 standard boxes of food at $2 20	$3 575 00	
1,274 standard boxes of food at 2 30	2,930 20	
353 standard boxes of food at 2 28	804 84	
Total disbursements		7,310 04
Balance		$ 593 80

F F Simpson M D, Treasurer,
5 Jenkins Arcade Bldg, Pittsburgh, Pa.

FOREIGN

Hospital Opened in Colon—The Samaritan Hospital, a private institution with twenty-five beds, has been opened in the city of Colon, Panama It is owned and operated under the direction of Drs S J Taylor and Harry Eno It is the first private hospital in the republic of Panama since the American occupation of the Canal Zone

Foot and Mouth Disease—In 1911 and 1912 Ireland had an epidemic of foot and mouth disease, and again in 1914 in a more severe form The disease appeared in England in the fall of 1913, and in January, 1914, the first case was reported in Ireland By June the loss from the disease had been estimated at $9,000,000 It was thought the disease might have been brought to Ireland by drovers from the lairages in England It was also suspected that the disease might have been brought in by straw packing from the continent

PARIS LETTER

Paris, Nov 25, 1915

The War

SCIENTIFIC INVENTIONS BEARING ON THE NATIONAL DEFENSE

The minister of public instruction in the new cabinet is a scientist, M Painleve, who is well known as a mathematician Believing that the problems of national defense call for the aid of all the intellectual forces of the country, M Painleve has just created in the department of public instruction, for the duration of the war, a division of investigations bearing on the national defense This division has the task of examining inventions and also of undertaking scientific researches which are called for by the war and navy departments

NERVOUS SYMPTOMS IN WOUNDED PATIENTS

The Societe de neurologie de Paris recently held two extraordinary sessions, under the presidency of Prof Gilbert Ballet, to study the methods of clinical examination and the course to be pursued in cases in which exaggeration or simulation of certain nervous symptoms is suspected in wounded patients The medical service had convoked the heads of all the military neurologic centers to take part in these sessions Such a meeting had been much desired by French neurologists who for a year had to treat wounded patients with nervous symptoms The opportunity to exchange scientific and practical opinions on the subject created much interest At the end of the session, the society passed the following resolutions, which were transmitted to the medical service

1 In each of the armies, neurologic and psychiatric centers, such as already exist in several of them, should be formed In such centers all patients affected with nervous and mental conditions and all those suspected of simulation or exaggeration should be examined The purpose should be, on the one hand, to recognize, before they are removed to the special centers of the interior, the patients affected with lasting organic lesions, and on the other hand to avoid the removal to the rear of patients suspected of simulation and exaggeration or affected with nonorganic conditions, which can be recognized, treated and cured very rapidly in the zones of the armies, as appears from results already obtained in existing centers (The Journal, Dec 11, 1915, p 2102)

2 Soldiers suspected of simulation or exaggeration or of voluntarily prolonging their nervous troubles should be sent to special services where they can be under competent medical oversight and severe military discipline at the same time Experience has shown the value of such measures in certain neurologic centers where they have been applied It would be desirable that such special services be attached to the military neurologic centers already existing, if the heads of these centers are able to operate them

3 The opinions of the physicians of the neurologic centers with regard to a soldier dismissed by them should be taken into account wherever the soldier may go

4 Under no circumstances, at present, should soldiers affected with psychoneuroses be sent for discharge to the committees that arrange discharges

5 In view of the great number of diagnostic errors in cases of wounded men with nervous symptoms, it would be desirable that in each region, or group of regions, neurologic experts should regularly visit all hospitals and other places where patients are under treatment These experts should make notes on each neurologic case for the information of the committees that arrange discharges and to enable the attending physicians to form an opinion of the propriety of sending the soldiers back to service or to one of the neurologic centers

6 In view of the delicate scientific and practical problems which daily present themselves with regard to soldiers in neurologic hospitals, it would be desirable that the heads of the neurologic centers should have the opportunity to meet from time to time in order to coordinate their efforts to render the course of action uniform

M Justin Godart, undersecretary of the military medical service, informed the Societe de neurologie de Paris that he was forwarding to the director-general of the medical service of the armies, with his approval, the resolutions passed by the society Experience has shown, he said, the justification for forming neurologic psychiatric centers in each of the armies So far as the second resolution is concerned, it would be simple to form, instead of special services, departments annexed to the neurologic centers operating under competent medical direction and with a more severe discipline Resolutions 3, 4 and 5 have his unqualified approval

As for Resolution 6 M Godart is ready to approve the meetings requested provided they are not too frequent

CASES OF DEAFNESS AND MUTISM FROM WAR ACCIDENTS

It is well known that the powerful explosives employed in the present war sometimes produce complete deafness and mutism unaccompanied by any apparent lesion When the patient does not recover from his mutism spontaneously in a few weeks, the case is almost always incurable Dr Marage has just made a report to the Academie des sciences on this subject He has devised a system of mechanical vibratory massage of the larynx and the sides of the neck Thus the external and internal muscles of the larynx are acted on At the end of a few days, the patients begin to talk, and at the end of three weeks they entirely recover their usual speech This applies to those who have been deaf and mute for four or five months, and in whom all other methods of treatment have failed

Dr Andre Castex recently read before the Academie de medecine a paper on the various kinds of deafness produced by the explosion of large projectiles Such cases are ordinarily due to the explosion of a shell which plows up the earth, throws a man several yards up into the air or buries him under a mass of earth Sometimes the noise of near battle is sufficient to make a combatant deaf These cases of war deafness, according to seventy-seven observations of Castex, may be divided into two principal classes (1) rupture of the tympanum and (2) rupture of the labyrinth 1 Rupture of the tympanum is produced especially when the projectile, ball or shrapnel strikes the temporal or mastoidean region or when a shell produces a slight concussion 2 Rupture of the labyrinth is observed when a shell of large caliber which shakes the whole trench sends a man into the air It often coincides with cerebral disturbance Prognosis is very grave for the hearing It has been necessary to discharge the greater number of soldiers affected with rupture of the labyrinth Auditive reeducation by the natural voice and, still more exercises in lip reading are the best means of compensating for this infirmity

THE WAR AND STUDENTS AT THE FACULTÉ DE BEYROUTH

M Barthe a deputy, reported to the minister of public instruction that many foreign students had been compelled by the closing of the Faculte de medecine de Beyrouth to discontinue their studies there The climate of Montpellier being the most similar to that of Beyrouth, M Barthe asked if the students from Beyrouth could not continue their courses at the Faculte de medecine de Montpellier The minister of public instruction replied that the students from Beyrouth might, with the consent of the department of foreign affairs carry on their studies either at Montpellier or any other university of their selection

RESUMPTION OF EXCHANGE OF SERIOUSLY WOUNDED PRISONERS

The next exchange of seriously wounded French and German prisoners will take place December 2 A train of wounded German prisoners will come from Lyons and one or two trains of wounded French prisoners from Constance The number of patients to be sent back to their country is not large because in the recent fighting the greater number of seriously wounded men were gathered in and cared for by their own armies and have not been made prisoners

ACUTE NEPHRITIS OBSERVED IN THE TROOPS IN THE FIELD

At the same session of the Academie de medecine de Paris, Drs J Parisot and Ameuille of Paris called attention to the fact that observations on the troops in the field have shown an altogether abnormal number of cases of apparently spontaneous acute nephritis, which might be called cryptogenetic, for their origin is very obscure These cases of nephritis have nothing in common with what has been called albuminuria of fatigue They are true nephritis accompanied sometimes by anasarca sometimes by serious uremic manifestations, too often terminated by death Because of their frequency, their seriousness and their rapid course and also because of deceptive symptoms which they often manifest at the outset they deserve much attention, it is important that they should be treated early Their seriousness, in fact, seems to increase in proportion as treatment is late From these facts one practical conclusion appears In spite of the difficulties in the way, physicians called on to give the first care to patients from the ranks should consider examination for albuminuria as important as for fever

PHARMACISTS IN THE ARMIES

M Derognat, a deputy has called the attention of the minister of war to the fact that pharmacists in the army, having no military grade, are subject to all the demands made on a mere orderly, such as sweeping and scrubbing rooms M Derognat asked if it would not be possible to give the pharmacists, even those of the second class, the rank of pharmacist *aide-major* or at least auxiliary pharmacist with the grade of adjutant while keeping them in the group of male nurses with whom they are already classed The minister replied that 304 pharmacists *aides-majors* of the second class (ranking as second lieutenants) have been appointed since May 7, 1915 Auxiliary pharmacists will be selected from the pharmacists of the first and second class as well as pharmaceutical students of three or even, under certain conditions, two years' school work, but these appointments will be made only as need for them arises

Use of Condensed Radium Emanation in Glass Tubes

Dr Debierre professor of anatomy at the Faculte de medecine de Lille, and Dr Regaud agrege professor of anatomy at the Faculte de medecine de Lyon, made a report to the Academie des sciences on the possibility of utilizing therapeutically in place of radium, radium emanation collected and condensed in glass receptacles chilled by immersion in liquid air Glass tubes containing radium emanation and sealed with a blow pipe constitute the most simple, economical, surest and most varied apparatus for biologic applications The only inconvenience of the employment of concentrated emanation is due to the fact that it produces a certain loss of radio-active energy from the incessant destruction of the emanation in the mother radium solution On the other hand the procedure presents the following advantages the assured security of the radium, which thus ceases to circulate among users, the variety of shapes for the apparatus in which it can be applied, finally the possibility of any physician being able to procure the active agent without acquiring the mother substance

Death of Professor J Ville

The death of Dr Jules Ville, professor of medical chemistry at the Faculte de Montpellier, is announced

Marriages

THOMAS HENRY BATES, M D, Madison, Fla, to Miss Mamie Fairfax Dunstan of Houston, Texas, in New Orleans, November 25

OLIVER AMES LOTHROP, M D, Boston, to Miss Edna M Sturk of Aylesford, N S, at Cambridge, Mass, November 24

PERCY EDWIN DUNLOP MALCOLM, M D, to Miss Janne Wolff both of New York City, at Montclair, N J., November 13

NELSON LEE ROY HELLER, M D, Dunkirk, Ind., to Miss Pauline Jeanette Current of Red Key, Ind, Octobe 22

LOUIS VAN PATTEN, M D., St Charles, Ill, to Mrs Caroline Gillette of Aurora, Ill., at Elgin, Ill, November 25

JOHN EDSON BOLENDER, M.D, Cadillac, Mich., to Miss Maud Kepple of Grand Rapids, Mich, November 25

JOSEF BENSEN SCHROCK, M D, to Miss Lois Estelle Duffie, both of Scottsbluff, Neb, at Omaha, December 2

GUY OTEY SHIREY M.D, Fort Worth, Texas, to Miss Louise Ball of New Boston, Texas, November 3

HARRY MOLLYNEAUX BROWN, M D, to Miss Reba Hildebrant, both of New Vienna, Ohio, November 30

ANTONIO B JANNARELLI, M D., to Mrs Sophia Johrous Monteleone, both of New Orleans, October 26

FREDERICK SMITH BAIRD, M D to Miss Mary Jane Lawrence, both of Bay City, Mich., November 27

WARFIELD THEOBALD LONGCOPE, M D., to Miss Janet Percy Dana, both of New York City, December 2

MARY MERRITT CRAWFORD M D, Brooklyn, to Mr Edward Schuster of New York City November 30

WILLIAM H TREIBLE, M D to Miss Camilla J Steig, both of York, Pa., in New York City, recently

ARRIE BAMBERGER, M D, to Miss Amelia Miriam Hitzelberger, both of Chicago, November 25

CHARLES E WHITEHEAD, M D, to Miss Eleanor M Flynn, both of Logan Mont, December 1

RALPH MONTGOMERY GOSS M D., to Miss Calenda King, both of Athens, Ga, November 24

GEORGE DAVID WOLF, M D., to Miss Rose Bonime, both of New York City, November 25

CLARENCE LEWIS WALTON, M D., to Miss Clara Marek, both of Chicago, December 2

Deaths

Ap Morgan Vance, M D University of Louisville, Ky, 1878, aged 61, a Fellow of the American Medical Association and president-elect of the Kentucky State Medical Association, president of the Jefferson County Medical Society, died at his home in Louisville, December 9 Dr Vance was born in Nashville, Tenn, May 24, 1854, received his preliminary education in New Albany, Ind, and was a student in medicine of Dr David W Yandell, one of the most distinguished surgeons of Louisville In addition to the society affiliations noted above, Dr Vance was a member of the American Orthopedic Association, American Gynecological Society and Southern Surgical and Gynecological Association He had served at various times as surgeon for the City Hospital, and Sts Mary and Elizabeth Hospital and had been chief surgeon of the Masonic Widows' and Orphans' Home for thirty-five years He was the only medical member of the special commission which built the new million-dollar Louisville City Hospital and was responsible for the general plans and scope of the building Professionally Dr Vance ranked as a pioneer in orthopedic surgery, and personally he was greatly esteemed and beloved

Abram Alexander Smith, M D Bellevue Hospital Medical College, 1871, aged 68, a Fellow of the American Medical Association, a member of the New York Academy of Medicine and American Climatological Association, attending physician to Demilt Dispensary from 1873 to 1879, a member of the staff of the New York Women's Hospital from 1875 to 1879, successively lecturer on clinical medicine, lecturer on materia medica and therapeutics and professor of materia medica and therapeutics in his alma mater from 1875 to 1892, professor of principles and practice of medicine and clinical medicine in the University and Bellevue Hospital Medical College since 1898, for many years consulting physician to Columbus Hospital, the Hospital for Ruptured and Crippled and Minturn Hospital, died at his home in New York City, December 13, from heart disease

William John Roe, M D Jefferson Medical College, 1895, aged 46, a Fellow of the American Medical Association, also a dentist, professor of surgical pathology and oral surgery in the Pennsylvania College of Dental Surgery, Philadelphia, first assistant demonstrator of anatomy and surgery in his alma mater, a member of the medical staff of the Philadelphia General Hospital, died in St Mary's Hospital, Rochester, Minn, November 27, from tuberculosis of the kidney

John R Rathmell, M D Starling Medical College, Columbus, Ohio, 1883, aged 63, professor of principles and practice of medicine and diseases of children, secretary and later dean of the faculty of the Chattanooga Medical College, a member of the staff of Erlanger Hospital, Chattanooga, formerly president of the Chattanooga Medical Society, the Chattanooga Board of Health and the Tennessee State Board of Health, died at his home in Chattanooga, December 2

Forrest Bedford Smith, M D University of Pennsylvania, Philadelphia, 1900, aged 47, a Fellow of the American Medical Association, local surgeon to the Southern Pacific System at Houston, Texas, and consulting surgeon to the Houston Infirmary, died in the Sunset Hospital, Houston, December 1, from acute gastritis for the relief of which operations had been performed without success

Ezra B Hiestand, M D Starling Medical College, Columbus, Ohio, 1863, Bellevue Hospital Medical College, 1872, aged 85, the oldest practitioner of Hardin County, Ohio, and a charter member of the Hardin County Medical Society, in honor of whose eightieth birthday anniversary a celebration was held in 1910, died at his home in Kenton, Ohio, November 28, from heart disease.

William Richter Longshore, M D Pennsylvania Medical College, Philadelphia, 1860, aged 77, a member of the Medical Society of the State of Pennsylvania, a veteran of the Civil War in which he served as surgeon of the Ninth Pennsylvania Volunteer Infantry, for many years surgeon of the Ninth Infantry, N G, Pa, died at his home in Hazelton, Pa., December 1, aged 77

Eugene James Gallagher, M D Albany (N Y) Medical College, 1892, aged 47, a member of the Medical Society of the State of New York, district health inspector of Yonkers, N Y, formerly chief of the Kingston, N Y., City Hospital and health officer of that city, died in the Polyclinic Hospital, New York City, December 3, from disease of the kidney

Asa Pingree Reed, M D Tufts College Medical School, Boston, 1895, aged 59, a member of the Maine Medical Association, formerly of Naples, Maine, but for the last three years a member of the staff of the Douglass Sanitarium, Dorchester, Boston, also a druggist and editor of the *Physicians' Drug News,* was found dead in his office, December 2

Jesse Porter Hendrick, M D University of Texas, Galveston, 1893, aged 50, a member of the State Medical Association of Texas and a well-known practitioner of Huntsville, who was operated on for appendicitis in a sanatorium in Houston, November 18, and was apparently doing well, died suddenly, November 22, from cerebral hemorrhage

James Walter Baird, M D College of Physicians and Surgeons, Baltimore, 1874, aged 65, formerly a member of the Medical Society of Virginia, died at his home near Waverly, Surry County, Va, November 30, from the effects of a gunshot wound of the head believed to have been self-inflicted while suffering from depression due to ill health

Joseph McDowell McKamey, M D University Medical College, Kansas City, Mo, 1910, aged 33, a member of the Kansas Medical Society, of Kingman, Kan, whose skull was fractured in a collision between his automobile and a railway train at a grade crossing at Pretty Prairie, Kan, died in a hospital in Kansas City, December 2

George Washington Welty, M D Bellevue Hospital Medical College, 1870, aged 70, a member of the Medical Society of the State of New York, for many years a member of the Brooklyn Charities Board and director of St Vincent's Home for Friendless Boys, Brooklyn, died at his home in that city, December 1, from heart disease

Lansing Van Auken, M D Albany (N Y) Medical College, 1892, a member of the Medical Society of the State of New York, pastor of the First Presbyterian Church at Watervliet, N Y, and inventor of a well-known shock absorber for automobiles, died at his home in Watervliet, November 27

Walter I Pennock, M D University of Pennsylvania, Philadelphia, 1888, aged 47, a Fellow of the American Medical Association and for twenty years a practitioner of Philadelphia, died at his home in that city, November 28, from a gunshot wound, self-inflicted, it is believed, with suicidal intent

William M Stratton, M D Northwestern University Medical School, Chicago, 1870, aged 71, formerly a member of the Minnesota State Medical Association and for more than forty years a practitioner of Granite Falls, died at his home in that place, November 9, from cerebral hemorrhage

Merritt Walter Hall, M D Chicago College of Medicine and Surgery, 1910, aged 31, a Fellow of the American Medical Association, of Chicago, died at the home of his mother in that city, December 4, from the effects of poison believed to have been self-administered with suicidal intent

Avery E Moore (license, Arkansas, 1903), aged 59, deputy auditor of state of Arkansas from 1898 to 1905, and auditor of state from 1906 to 1910, when he resigned to become a member of the state tax commission, died at his home in Enders, Ark, November 22, from tuberculosis

Jonas Muller, M D University and Bellevue Hospital Medical College, 1913, aged 25, president of the medical board of the Bedford Hospital and Dispensary, Brooklyn, died in the Jewish Hospital, Brooklyn, December 2, two weeks after a surgical operation on the nose

Benjamin L Smith, M D University of Maryland, Baltimore, 1859, aged 77, a member of the Medical and Chirurgical faculty of Maryland, twice a member and for five terms chief clerk of the House of Delegates, Maryland, died at his home in Madison, Md, November 23

John A. Brill, M D Cincinnati College of Medicine and Surgery, 1884, aged 64, a member of the Illinois State Medical Society and a well-known practitioner of the northwest side of Chicago, died at his home in that city, December 4, from cerebral hemorrhage

William H Bogle, M D Jefferson Medical College, 1885, aged 58, for several years division surgeon for the Missouri Pacific Railway and local surgeon for the Santa Fe and Burlington systems at Atchison, Kan, died at his home in that city, November 30

John William Wickham, M D Vanderbilt University, Nashville, Tenn, 1885, aged 55, of Palmyra, Tenn, who was shot November 29 in a quarrel at Hackberry, Tenn., b Charles Baggett, died from his wounds in a hospital at Nashville, November 30

Calvin Starr, M.D. Western College of Homeopathic Medicine, Cleveland, 1851, aged 93, a practitioner of Iowa City, Iowa, from 1857 to 1877 and thereafter a resident of Nebraska City and Beatrice, Neb., died at his home in the latter city, November 25.

Aaron B. McCallon, M.D. College of Physicians and Surgeons, Dallas, Texas, 1907, aged 37, of Cresson, Texas, a member of the State Medical Association of Texas, was shot and instantly killed in an affray on the main street of Cresson, September 24.

Elmer E. Horn, M.D. Medico-Chirurgical College of Philadelphia, 1889, aged 53, surgeon to the North Pennsylvania Hospital and Sanatorium, later a practitioner of Linden, Pa., died in the Williamsport (Pa.) Hospital, December 2, from carcinoma.

Ernest David Disbrow, M.D. Rush Medical College, 1880, aged 57, a member of the Illinois State Medical Society, formerly secretary of the Grand Rapids (Mich.) Academy of Medicine, died at his home in Chicago, December 4, from cerebral hemorrhage.

Nathaniel Ritter, M.D. Jefferson Medical College, 1861, aged 76, for fifty-four years a practitioner of Lehigh County and Allentown, Pa., was instantly killed November 21 near Amityville, Pa., by the overturning of an automobile in which he was riding.

Commodore Perry Devore, M.D. Eclectic Medical Institute, Cincinnati, 1871, aged 77, for many years a practitioner of Sutter, Calif., but for the last nine years a practitioner of Drain, Ore., died at his home in that place, November 19, from heart disease.

Morgan Propst, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1884, aged 65, physician of Fillmore County, Neb., and a member of the Board of Health of Geneva, Neb., died at his home in that city, October 9, from uremia.

John O. Foree, M.D. University of Louisville, Ky., 1888, aged 60, a member of the Tennessee State Medical Association, a well-known practitioner and druggist of Athens, Tenn., died at his home in that place, November 26, from pneumonia.

Gregory Paul (examination, N. Y., 1888), aged 57, a native of Asia Minor and an alumnus and for many years professor of medicine in the University of Aintab, Turkey, died in the Post-Graduate Hospital, New York City, November 23.

James A. Porter, M.D. Detroit Medical College, 1869, aged 70, for many years a practitioner of Brooklyn, Mich., and a specialist on diseases of the eye and ear, was found dead, from heart disease, in his barn in Brooklyn, November 27.

Laughlin Sinclair, M.D. University of Michigan, Ann Arbor, 1864, Victoria College, Coburg, Ont., 1867, aged 76, dean of the medical profession of Bruce County, Ont., died at his home in Walkerton, Ont., September 21, from uremia.

Henry Harrison Riegel, M.D. Jefferson Medical College, 1857, aged 79, continuously a practitioner of Pennsylvania for fifty-eight years, a Fellow of the American Medical Association, died at his home in Catasauqua, November 25.

John Antis, M.D. College of Physicians and Surgeons of the Western District of New York, Fairfield, 1837, aged 98, since 1845 a practitioner of Grundy County, Ill., died at the home of his daughters in Mazon, Ill., November 25.

George B. Newell Clow, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1880, Rush Medical College, 1883, aged 59, a Fellow of the American Medical Association, of Oakland, Calif., died in Palo Alto, Calif., November 23.

Samuel A. Woods, M.D. Jefferson Medical College, 1900, aged 39, a Fellow of the American Medical Association, a well-known practitioner of Sharon and coroner of Mercer County, Pa., died at his home in Sharon, November 24.

Samuel Milton Littlefield, M.D. Rush Medical College, 1884, aged 55, a member of the Iowa State Medical Society and a practitioner of Andrew, Iowa, died in the Iowa Sanitarium, Maquoketa, November 30, from nephritis.

Beatty R. Spurr, M.D. Transylvania University, Lexington, Ky., 1848, aged 90, for more than thirty years a practitioner of Greendale, Ky., and later a resident of Stroud, Okla., died at his home in that city, November 4.

Thomas Jefferson Upshaw, M.D. American Medical College, St. Louis, 1890, aged 71, a veteran of the Civil War and for many years a practitioner of St. Louis, died at the home of his son in that city, November 22.

James Mack Sharet, M.D. University of Tennessee, Nashville, 1874, aged 44, a member of the Florida Medical Association, of Milton, Fla., died in the Pensacola Hospital, November 11, from intussusception.

Albert Augustus Lindabury, M.D. Baltimore Medical College, 1886, Hahnemann Medical College, Philadelphia, 1890, aged 53, of Scranton, Pa., died in the Scranton State Hospital, November 22, from diabetes.

Francis A. Mitchell, M.D. University of Louisville, Ky., 1883, aged 82, for many years a practitioner and druggist of New Albany, Ind., died at his home in that city, November 25, from cerebral hemorrhage.

Adelard M. Brunelle, M.D. University of Minnesota, Minneapolis, 1886, aged 58, a member of the Minnesota State Medical Association, died at his home in Cloquet, Minn., November 25, from heart disease.

Wilkins T. Brandon, M.D. Vanderbilt University, Nashville, Tenn., 1880, aged 56, formerly a member of the State Medical Association of Texas, died at his home in Fulbright, Texas, October 19, from nephritis.

John Patrick Stanton, M.D. University and Bellevue Hospital Medical College, New York City, 1899, of Scranton, Pa., was instantly killed in an automobile accident near Wilkes-Barre, Pa., November 24.

Charles F. O'Neill, M.D. Michigan College of Medicine and Surgery, Detroit, 1897, aged 44, of Middleton, Mich., died in St. Mary's Hospital, Grand Rapids, Mich., November 19, from pulmonary embolism.

Merle Cornelius Newkirk, M.D. Johns Hopkins Medical School, Baltimore, 1913, aged 28, of Sherman, N. Y., died at the home of his parents in Ellicottville, N. Y., November 23, from disease of the throat.

Clifford J. Oliveros, M.D. Baltimore University School of Medicine, 1890, aged 49, of Columbia, S. C., a specialist on diseases of the eye, ear, nose and throat, died at his home in Columbia, November 17.

C. N. Frazier (registration, Oklahoma, 1908), a member of the Oklahoma State Medical Association, aged 37, died at his home in Hugo, Okla., September 3, from congestion of the liver.

Orson Gregory Dibble, M.D. New York University, New York City, 1869, aged 75, for fifteen years health officer of the town of Pompey, N. Y., died at his home, November 24.

William Henry Morse, M.D. Bellevue Hospital Medical College, 1871, aged 65, died at his home in Bronx Borough, New York City, November 26, from cerebral hemorrhage.

J. Benson Hill (license, Michigan, twelve years of practice, 1900), aged 71, for twenty-seven years a practitioner of Ovid, Mich., died at his home in that place, November 23.

Thomas Jefferson Sherlock, M.D. Eclectic Medical Institute, Cincinnati, 1893, aged 70, of Hart, Mich., died in Butterworth Hospital, Grand Rapids, Mich., November 20.

Edward M. Royall, M.D. Medical College of the State of South Carolina, Charleston, 1849, aged 88, died at his home in Mt. Pleasant, S. C., about November 23.

William D. Chase, M.D. Hospital College of Medicine, Louisville, 1904, aged 40, was found dead in bed at his home in Milligan College, Tenn., November 21.

John A. Welch, M.D. Central College of Physicians and Surgeons, Indianapolis, 1883, aged 68, died at his home in Lena, Ind., November 18, from nephritis.

Henry Eugene Robinson, M.D. University of Colorado, Boulder, 1911, aged 30, of Ogden, Utah, died in Hooper, Utah, November 20, from tuberculosis.

Samuel J. Stone, M.D. Chicago College of Medicine and Surgery, 1914, aged 35, died suddenly in his office in Butte, Mont., October 3, from uremia.

David Yiengst Roebuck, M.D. University of Pennsylvania, Philadelphia, 1866, aged 71, died at his home in Dalton, Ohio, about November 20.

Peter H. Banta, M.D. Detroit College of Medicine, 1900, aged 41, died at his home in De Witt, Mich., November 26, from disease of the stomach.

Leopold Charles Shulke, M.D. St. Louis College of Physicians and Surgeons, 1905, aged 32, died at his home in Decatur, Ill., November 19.

Bezaleel Bell Andrews, M.D. Hahnemann Medical College, Chicago, 1878, aged 70, died at his home in Nemaha, Neb., about November 16.

A. W. Goodman, M.D. University of Nashville, Tenn., 1862, aged 75, died at his home in Elkton, Ky., November 19.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

OZOMULSION

Ozomulsion is one of several nostrums put out by the T A Slocum Company of New York City Nearly ten years ago Mr Samuel Hopkins Adams (*Collier's*, Jan 13, 1906) had something to say about the Slocum nostrum factory and the man who was at that time proprietor of the concern, one A Frank Richardson To quote from part of Mr Adams' article

> "The Slocum Consumption Cure proper consists of a gay-hued substance known as 'Psychine' Psychine is about 16 per cent alcohol, and has a dash of strychnin to give the patient his money's worth Its alluring color is derived from cochineal It is 'an infallible and unfailing remedy for consumption' Ozomulsion is also a sure cure, if the literature is to be believed To cure one's self twice of the same disease savors of reckless extravagance, but as 'a perfect and permanent cure will be the inevitable consequence,' perhaps it's worth the money It would not do to charge Dr T A Slocum with fraud, because he is, I suppose, as dead as Lydia E Pinkham, but Mr A Frank Richardson is very much alive, and I trust it will be no surprise to him to see here stated that his Ozomulsion makes claims that it cannot support, that his Psychine is considerably worse, that his special cure offer is a bit of shameful quackery, and that his whole Slocum Consumption Cure is a fake and a fraud so ludicrous that its continued existence is a brilliant commentary on human credulousness"

The nostrum, "Psychine" which, previous to the passage of the Food and Drugs Act, was labeled "An Infallible Remedy for Consumption" to be later modified to "Wonderful Remedy for Consumption" and still later to be changed to "Tonic Appetizer and Aid to Digestion" has, apparently, not occupied much space in the public prints during the last few years Ozomulsion, however, has, apparently, been kept alive by advertising In April, 1915, the United States Attorney for the Southern District of New York, acting on a report by the Secretary of Agriculture, filed two informations against the T A Slocum Company, alleging that the concern had shipped two consignments of Ozomulsion from the state of New York into the state of Tennessee in violation of the Food and Drugs Act The product was declared misbranded in both informations on the ground that the therapeutic claims made on the carton were "false and fraudulent" Moreover, the government declared that these claims

> " were applied to said article knowingly and in reckless and wanton disregard of their truth or falsity, so as to represent falsely and fraudulently to the purchasers thereof, and create in the minds of purchasers thereof the impression and belief that it was in whole or in part composed of, or contained, ingredients or medicinal agents effective for permanently curing tuberculosis, consumption, phthisis, whooping cough, pneumonia, and all kinds of lung diseases, St Vitus's dance, epilepsy, night sweats, and malaria, when, in truth and in fact, said article was not in whole or in part composed of and did not contain ingredients or medicinal agents effective for curing tuberculosis, consumption, phthisis, whooping cough, pneumonia, and all kinds of lung diseases, St. Vitus's dance, epilepsy, night sweats, and malaria"

The product was declared misbranded further because of the claims made that Ozomulsion would cure pneumonia and prevent the development of consumption "when in truth and in fact, said article was not in whole or in part composed of, and did not contain, ingredients or medicinal agents effective for curing pneumonia or for preventing the development of consumption following pneumonia, or at any other time"

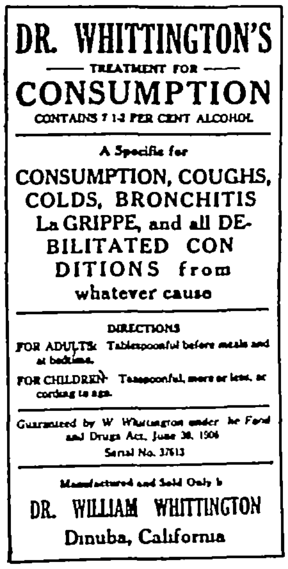
The analysis made by the federal chemists was summed up in the statement "sample appears to be an emulsion of cod liver oil and glycerin with the addition of phosphorous compounds of calcium and sodium" The chemists also call attention to the fact that their tests indicated that the cod liver oil used in this emulsion "had not been ozonized" This claim about "ozonizing" the oil used in the nostrum has long been one of the talking points, in fact the old trade-package declared that Ozomulsion was a combination of ozone, cod liver oil and other ingredients "OZONIZED BY ELECTRICITY (Slocum's French method) for the purpose of replacing by ozone the oxygen consumed by the system in digesting cod liver oil"

The T A Slocum Company pleaded guilty to the government's charges and was fined $80 This can hardly be considered an excessive punishment for a concern engaged in the business of defrauding the sick in general and consumptives in particular The details of this case will be found in *Notice of Judgment 3979*, issued Oct 21, 1915

DR WHITTINGTON'S TREATMENT FOR CONSUMPTION

"Dr Whittington's Treatment for Consumption" is, according to the label, "manufactured and sold only by Dr William Whittington, Dinuba, Cal" According to our records, Dr William Whittington was graduated by the Missouri Medical College of St Louis, Mo, in 1880 and was licensed to practice in California in 1891 The preparation, which admittedly contains 7 5 per cent alcohol, is labeled

> "A Specific for Consumption, Coughs, Colds, Bronchitis, La Grippe and All Debilitated Conditions from whatever cause"



DR. WHITTINGTON'S
TREATMENT FOR
CONSUMPTION
CONTAINS 7 1-2 PER CENT ALCOHOL

A Specific for
CONSUMPTION, COUGHS,
COLDS, BRONCHITIS
La GRIPPE, and all DEBILITATED CONDITIONS from
whatever cause

DIRECTIONS
FOR ADULTS: Tablespoonful before meals and at bedtime.
FOR CHILDREN: Teaspoonful, more or less, according to age.

Guaranteed by W Whittington under the Food and Drugs Act, June 30, 1906
Serial No. 37613

Manufactured and Sold Only by
DR. WILLIAM WHITTINGTON
Dinuba, California

Reduced photographic facsimile of the label on Whittington's "consumption cure" It obviously violates the federal Food and Drugs Act.

The bottle contains about twelve ounces of a brown, sirupy liquid and sells for $5 00 In reply to an inquiry sent to Whittington by a supposedly consumptive layman, there came a letter signed "W Whittington," reading in part as follows

> " I have a treatment that DOES CURE CONSUMPTION The cost of the treatment is $20 00 for each month's treatment You can get it one month at a time or more as you like If you wish to try it you better take one month's treatment at first to see what it will do for you But if you take it for one month I know you will send back for more For I know it will do you good For THIS IS THE ONLY TREATMENT THAT DOES REALLY CURE CONSUMPTION As to how long you will need to take it depends on your condition It takes from three to six months to cure If you have not had it long three months may cure you If you are very bad it will take longer "—[Capitals ours —Ed]

Requests have come in at different times for information regarding this nostrum A bottle of Whittington's "Specific" was examined in the Chemical Laboratory of the American Medical Association The condensed report of the chemist follows

"The liquid had an odor of raspberry and prunes and also somewhat vinous characteristics, with a tannin-like taste The reaction toward litmus was acid The specific gravity at 15 6 C was 1 0963 The weight of ash from 100 c c was 0 73 grams Qualitative tests indicated the presence of alcohol, magnesium, tannin and other vegetable acids, acetate, sugar, glycerin, and traces of calcium, potassium and sodium Tests for the following yielded negative results heavy metals, haloids, sulphates, alkaloids, emodin-bearing drugs, benzoate, cinnamate, salicylate and glycyrrhiza From this analysis it appears that 'Dr Whittington's Treatment for Consumption' is a flavored syrup, devoid of potent ingredients other than alcohol"

Selling flavored syrup as a "cure" and "specific" for consumption is a disreputable enough business under any circumstances, but what shall be thought of a physician who will carry on such a trade? Whittington's case is of more than ordinary interest to the medical profession because the man is not only a member of that profession, but a member of the Medical Society of the State of California.

ROGERS' CONSUMPTIVE CURE AND COUGH LOZENGES

"Rogers' Consumptive Cure and Cough Lozenges" and "Rogers' Inhalant" were two products sold by the M. J. Rogers Medical Company of Lewiston, Maine. According to a government report the former product bore on the labels such claims as:

> Rogers Consumptive Cure and Cough Lozenges. Are good for Lung Troubles of all kinds.
>
> For Whooping Cough they are a ready relief.'
>
> For Coughs, new and of long standing they are unsurpassed.
>
> They can be *confidently relied upon* as an *infallible cure* for all pulmonary troubles of every description.'
>
> warranted to effect entire and permanent cures in every case curable at *all*.'

The latter preparation bore such claims as:

> Rogers' Inhalant Is the Greatest Discovery of Modern Medical Science for the positive cure of Catarrh, Asthma, Hay Fever, Rose Cold, Cold in Head, Influenza, Headache, Pneumonia, Bronchitis, Diphtheria, Hoarseness, Loss of Voice, Bleeding of the Lungs, Pleurisy, and all diseases leading to Consumption.

The government officials filed an information against the M. J. Rogers Medical Company alleging that these two products, which had been shipped in interstate commerce, were misbranded because of the false and fraudulent claims for curative effect that had been made for them. The government chemists, who analyzed both the lozenges and inhalant, reported that the former "consists of sugar lozenges containing a small amount of gum and a trace of oil of rosemary" and that the latter was "an alcoholic solution of volatile oil, chiefly rosemary." The false and fraudulent therapeutic claims made, only a few of which we have quoted, were declared by the federal officials to have been applied to the articles "knowingly and in reckless and wanton disregard of their truth or falsity." This concern did not plead guilty but entered a plea of *nolo contendere* which was equivalent to admitting that they were not prepared to substantiate the claims they had made. The M. J. Rogers Medical Company was fined $15, the case being described in *Notice of Judgment 3986* issued Oct. 21, 1915.

Correspondence

The "Autolysin" Treatment for Cancer

To the Editor:—In the Nov. 6, 1915, issue of The Journal there was printed a special article by Dr. Richard Weil regarding the autolysin treatment of cancer. In this article Dr. Weil attempts to analyze the situation respecting autolysin, the method of its introduction in the General Memorial Hospital and the nature of the patients who were treated in this institution, and states what his own conclusions are regarding its merits. It has been difficult for me to believe that Dr. Weil would so wilfully misrepresent the entire situation.

Dr. Weil was a member of my department in the medical school for many years, so that I am well acquainted with him. I cannot believe, however, in this instance that he is acting solely from good motives in making the statements that he has printed. I know, personally, that his present statements are not at all in accord with the views which he expressed to me at the time the work was in progress at the hospital.

It is impossible for me to make an adequate reply to his statement without analyzing it in detail. Such a statement has been prepared and is evidently in its length and its character unsuitable for publication in The Journal. It will, however, be printed elsewhere.

The misrepresentations which Dr. Weil has made occur not only in the form of direct categorical statements but also in the inferences which a reader unacquainted with the matter would necessarily draw from the article. These misrepresentations include such matters as the circumstances surrounding the introduction of the remedy into the hospital, the character of the patients treated in the institution and the results obtained, as well as his own relation to the experiments. He has, furthermore, misrepresented my own ideas and statements with respect to the effects produced by the remedy and the limitations surrounding its use. He has likewise made statements from which the only inference that can be drawn is that the remedy is withheld from the general use of the medical profession and that no patients can obtain this treatment except by paying very large fees. Such inferences are unjust.

A considerable amount of space is devoted to pictures and reading matter concerning a patient who received one injection of autolysin at this office and later went to the Memorial Hospital. It would appear from what Dr. Weil has said that the circumstances which he relates concerning this patient are circumstances for which I am personally responsible. I can only state in this connection that I have printed two articles in a medical journal stating my own position with regard to the autolysin treatment, and that I disclaim all responsibility for newspaper or magazine articles which have appeared in the past or may appear in the future respecting this matter.

The final conclusion which Dr. Weil draws is that from a long observation he believes the method is useless. I think it is only fair to point out that Dr. Weil's long observation consists in never having administered a single dose of autolysin and in having given very superficial examination to a few patients in an advanced condition of inoperable cancer during the early developmental period of the treatment. Final conclusions in my judgment cannot be based on such data.

Honest criticism of this method of treatment, based on adequate experience, is to be welcomed. Untruth and misrepresentation do not contribute to the progress of medical affairs in this instance to any greater degree than they have in the past. My own experience justifies me in the belief that the autolysin method of treating inoperable cancer has decided value in ameliorating the distressing conditions in a considerable percentage of cases.

S. P. Beebe, M.D., New York.

Removal of Thyroid in Diabetes

To the Editor:—Encouraged by the experience of having several cases of glucosuria associated with exophthalmic goiter clear up when the hyperthyroidism was corrected, two cases of diabetes in young subjects with no goiter symptoms were treated by removing the greater portion of the thyroid gland. The results were as follows: One was restored to complete carbohydrate tolerance, the other to a tolerance of 9 ounces of carbohydrates per day. As only a few months have passed since these cases were so treated, end-results are yet to come, but until such time, together with a record of more cases, please publish this to establish my priority should the idea prove of value.

J. Christopher O'Day, M.D., Portland, Ore.

"Sewage" and "Sewerage"

To the Editor:—In your effective educational work would it not be proper to clarify an alliterative entanglement? The two nouns "sewage" and "sewerage" offer difficulties to many, as does the impossible "preventative." Sewage flows within the sewerage, the former is the liquid, the sewerage being the system of pipes which carries it off. The only sewage system is the intestinal canal, but a sewerage system is always the mains, conduits and other pipes *in the ground*. *Sewage disposal is any* method of depositing or getting rid of the excreta, whether by privy, by the use of sewers or a sewage treatment plant. If the sewers are dug up out of the ground and thrown away, that would constitute sewerage disposal Very frequently one sees the incorrect expressions "sewerage treatment" and "sewerage purification" Sewage is the liquid discharge—sewerage always the pipe, the connected sewers

Harold B Wood, M D,
Health Officer and Secretary, Department of Health, Topeka, Kan

Music as a Therapeutic Agent

To the Editor —I desire information concerning the use of music by the medical profession Some time ago Dr Kane reported his use of music as an aid in the operating room, and also in the wards of the hospital His report was followed by a series of humorous comments, which did not take the effort at all seriously As far as I know, the hospitals for the insane are practically the only ones that make extensive use of music as a therapeutic agent, but I should like to receive further first-hand information Just a little thought ought to convince any one that music could be used on logical grounds much more frequently than it is at present

Theodore Zbinden, M D, Toledo, Ohio

DROPPING OF PULSE BEATS

To the Editor —Please explain the cause or causes for the dropping of pulse beats at the wrist every third or fifth beat In many of these cases auscultation reveals only a lack of full contraction of the left ventricle, with no disturbance of rhythm in other respects Does it indicate degeneration of the musculature of the heart or merely a nervous manifestation? Is digitalis the best treatment?

G A Hill, M D, Philadelphia

Answer —By far the most common cause (in about 90 per cent of cases) of the dropping of pulse beats at the wrist is the occurrence of premature contractions or extrasystoles Normally the heart beat is induced in the sinus node (Keith-Flack), situated in the wall of the right auricle, and spreads over the heart from auricles to ventricles in an orderly sequence and at definitely timed intervals This sinus node is often designated as the pace maker of the heart In the case of extrasystoles an (ectopic) impulse arises early in diastole in some other portion of the heart which is more irritable than the sinus node This abnormal impulse causes the heart to beat too soon, or before the normal excitation from the pace maker is due Hence the volume of blood discharged by the ventricles is less than normal, and often is not of sufficient volume to produce a pulse wave at the wrist At other times the contraction of the ventricle may not overcome the pressure in the aorta, and in this event there is no pulse wave, and auscultation reveals only the first sound of the heart

In a small group of cases of extrasystole there is no evidence of cardiac disease In another group there is disease in another part of the body which could easily be accompanied by a pathologic condition of the heart Some of the most common of these are bronchitis, pulmonary emphysema, pulmonary tuberculosis, toxemia, exophthalmic goiter and gastric ulcer In the majority of cases, however, there is distinct cardiac involvement, as in myocarditis, valvular disease, acute endocarditis, arteriosclerosis or angina pectoris

Another cause for the dropping of pulse beats at the wrist is the condition of gross irregularity of the heart known as auricular fibrillation Here the auricle does not beat in response to the pace maker, but is in a state of fibrillation Only a few of these auricular contractile waves pass through the auriculoventricular bundle and cause ventricular contraction, but these are very irregularly timed, and may follow each other so soon as not to cause ventricular contraction of sufficient volume to produce a pulse wave at the wrist or even to raise the aortic valves In all of these cases there is more or less myocardial insufficiency, especially of the auricles

Finally, partial heart block may occasion the dropping of ventricular beats In this condition the auricles beat normally in response to impulses originating in the sinus node, but there is impairment in the conduction of the impulse through the auriculoventricular bundle Each succeeding impulse is delayed more at the bundle until an impulse fails to get through, and a ventricular contraction is missed The repetition of this process results in periodic failure or ventricular contraction and the consequent dropping of pulse beats at the wrist

It is impossible to generalize on the treatment of these conditions This must depend largely on the concomitant disease When there is evidence of myocardial insufficiency or loss of cardiac tone, digitalis may be of value

Cardiac irregularities and their treatment were discussed recently in an editorial on "The Rhythm of the Heart" (The Journal, Oct 21, 1915, p 1462) An excellent discussion of this subject will be found in Thomas Lewis' "Clinical Disorders of the Heart Beat," Edition 2, Shaw & Sons, London

MIST. HELONIN COMP (SCHLOTTERBECK'S)

To the Editor —Please give me any information you have about Compound Mixture of Helonin (Schlotterbeck & Foss, Portland, Me)

E F Howard, M D, Vicksburg, Miss

Answer —So far as we know, the only available information regarding the composition of Schlotterbeck's Mist Helonin Comp is the statement in a circular that the "active ingredients are Helonin, Senecin, Avenin," and the declaration on the label that it contains 45 per cent alcohol That is, apparently we are to assume that the mixture contains unspecified amounts of some kind of derivatives (claimed to be "resinoids") of false unicorn (*Helonias dioica*), liferoot (*Senecio aureus*) and oats (*Avena sativa*) Oats are practically devoid of resin, but this fact and the failure of the manufacturers to state the quantities are unimportant in view of the further fact that false unicorn, liferoot and oats are generally recognized as worthless drugs Essentially, Mist Helonin Comp appears to be a "bracer" nostrum The alcohol content is that of strong whisky The mixture is highly flavored and would undoubtedly be relished by those to whom alcoholic drinks appeal, while the practically inert drugs contained in it would not in the least interfere with its use as a cordial It is impossible to condemn too strongly the recommendations that it be given to young girls and pregnant women The recommendation that in dysmenorrhea teaspoonful doses should be given "every fifteen or twenty minutes until relief is obtained" means, of course, until the patient is stupefied or drunk On the basis of the information supplied by the manufacturers, Mist Helonin Comp may be classified as a vicious and a worthless nostrum—unless we regard the alcohol as of value

COAGULEN

To the Editor —Will you kindly refer me to literature on the product coagulen? Have there been any articles published about the use of this preparation in pulmonary hemorrhage? If so, what?

John J Lloyd, M D, Catawba Sanatorium, Va

Answer—The subject appears to be still in an experimental stage The only experimental work done on animals thus far seems to be that reported by Fonio, one of the discoverers of coagulen He found that the coagulability of the blood was increased for only an hour after intravenous injection of the substance

The other papers are reports of clinical experience, and the only ones that deal with the treatment of hemoptysis with coagulen are those of Juliusburger, Hotz, and Riedl Each of these authors reports on one case only of hemorrhage of the lungs treated by intravenous injections of coagulen The case of Riedl was that of a hemophilic who had severe pulmonary hemorrhages In all three cases the hemorrhages, which were occurring nearly every day, were checked after its use and did not recur within six weeks after the injection Of course, little significance can be attached to clinical cases observed singly, especially when, as in the present case, the probability of any connection between the remedy and the results attributed to it is discounted by animal experiment

These three clinicians noted no bad general effects following the intravenous injection of coagulen, nor have any cases of thrombosis or embolism been reported Fonio himself, however, has noted a kind of collapse effect following the use of coagulen on animals It is this fact which has deterred Albrecht from making use of coagulen intravenously He found that it had little effect on arterial or venous hemorrhages because the coagula produced by the coagulen are washed away by the oncoming blood

A description of coagulen appeared in The Journal, Sept. 25 1915, p 1111

Below is a list of the more accessible papers and reports on coagulen that have appeared during the last two years

INCOMPATIBILITY OF QUININ WITH ASPIRIN AND OTHER ORGANIC ACIDS

To the Editor —In the *Bulletin of Pharmacy* for November is an article relative to the incompatibility of aspirin and quinin, and the report of a death supposed to have been caused by this combination What is your opinion on this question?

A. P Standard M D, Macomb Ill

To the Editor —My attention has recently been called to the possibilities of the formation of a poisonous compound, when aspirin and quinin are administered together or near each other I have been informed that there have been a few fatalities and a number of nearly fatal cases resulting from this combination If such is possible I would be glad to have more information in regard to the matter and believe there are others who would be very glad to learn this through The Journal, rather than by the personal experience of having a patient die from such a combination H F T Iowa.

Answer —It has been known for a number of years that, by long-continued heating with glacial acetic acid or by fusion of the alkaloidal salts, some of the cinchona alkaloids may be converted into isomeric products which possess extremely poisonous properties Experiments have also shown that, by acting as catalyzers, slightly dissociated acids, such as acetylsalicylic (aspirin), citric, malic, acetic or tartaric acid under the influence of heat may convert quinin into its poisonous isomer, quinotoxin, and cinchonin into cinchotoxin At the temperatures of from 98 to 102 C (208 4 to 215 6 F) the conversion is practically quantitative, at 37 C (98 6 F—normal body temperature) the reaction goes on much more slowly, amounting to about 2 per cent in forty-eight hours The danger of poisoning through conversion of quinin into quinotoxin in the body cannot be great, but it is well to keep the possibility in mind The formation of a dangerous amount of the poisonous product would probably be greatly favored if the mixture—quinin and aspirin, for instance—had been made up for some time Suspensions of the alkaloid in flavored syrups with organic acids, etc. might be regarded with suspicion, likewise elixirs such as iron, quinin and strychnin, which usually contain citrates or tartrates The foregoing applies especially to the alkaloid and to such salts as quinin tannate Since conversion into the toxic isomer does not take place appreciably with an excess of strong mineral acid, there could be but little danger from the administration of the mineral acid alkaloidal salts such as quinin sulphate.

The subject has not been studied sufficiently to make it possible to decide in each case of supposed quinin poisoning whether the toxic symptoms were due to overdose, to idiosyncrasy or to formation of quinotoxin or cinchotoxin in mixtures administered

HARRISON NARCOTIC LAW AND THE DELIVERY OF DRUGS

To the Editor —Would it be a violation of the Harrison law for a druggist to fill a prescription that I give him for a patient of mine and send it to the patient by mail R F D? Every farmer in this county gets his mail by rural route and frequently it is a great convenience to send medicine by mail. It saves them a trip to town

R. D Z

Answer.—The Harrison Narcotic Law makes no provisions regarding the manner in which the drug shall be delivered to the patient by the druggist. After the druggist has filled the prescription, he may deliver it to the patient in person, by messenger, by mail or by express The object of the law is to secure a written record of every transaction involving the drugs covered by the law

Miscellany

America and the World's Supply of Cinchona Bark

That the cinchona tree is indigenous to South America is well known It is not so well known that within the lifetime of persons yet living the American continent has ceased to be a considerable factor in the world's supply of cinchona This fact is brought home to us today by the present high price of quinin (editorial, The Journal, Dec 4, 1915, p 2010)

There are many species of cinchona, a number of which yield varying amounts of alkaloids, while others are of little or no value. Commercial cinchona bark today, however, consists chiefly of red cinchona, yielded by *Cinchona succirubra,* and yellow cinchona or Calisaya bark, yielded by *C calisaya* and *C ledgeriana* These two barks are described in the U S Pharmacopeia

All the species of cinchona are natives of the Andean regions of South America between latitude 19 south and 10 north They have never been found native elsewhere, though some parts of Mexico are said to be well adapted to their growth (Markam, C R Peruvian Bark) For a long time the bark was collected only from the region around Loxa or Loja, Ecuador, whence came the famous bark that cured the Countess of Chinchon Later, forests were discovered elsewhere and worked out with ruthless waste Prospectors, it seems, sought new cinchona regions as they would have searched for gold, and having found a forest, exhausted it without thought for the morrow The *cascarilleros* (bark collectors) gathered the bark either by stripping the tree as it stood, or by felling it and then stripping it, new trees were never planted to take the place of those destroyed In 1735, Ulloa reported to the Spanish government that these wasteful practices would undoubtedly exterminate the forests about Loja in time. He suggested that the Corregidor of Loja should appoint an overseer of the forests whose duty it should be to see that a cinchona tree was planted in place of each one cut down This salutary rule, however, was not enforced, and sixty years later Humboldt reported that 25 000 trees were felled in a single year Sir Clements Markham, who saw the forests in the middle of the last century, believed that they were not likely to become actually exterminated unless the method of stripping the standing tree was followed exclusively This left the tree to be destroyed by rot and insects If it were felled very near the ground, sprouts would be sent up to take its place The more probable danger, Markham thought, was that of periods of scarcity during the time while young forests were growing up Nevertheless, Wellcome ('The Cinchona Forests of South America,' *Popular Science Monthly*, August 1880, p 507), who visited the cinchona regions after Markham's time (in 1879), was very pessimistic as to their future It is said that when the South American countries, especially Bolivia, desired to undertake the cultivation of cinchona, they sent abroad to secure seeds from the foreign plantations that were by that time flourishing (National Standard Dispensatory, article on cinchona, p 448)

It seems probable that the high prices of quinin during the Civil War were due largely to actual scarcity of cinchona bark, and possibly in some degree to interference by the South American governments with the bark export trade At all events the world would probably have been suffering long since from a quinin famine if it had not been for the cultivation of cinchona outside of South America Various men of different nationalities had suggested or attempted its domestication but the achievement was difficult, for, apart from the natural obstacles in the way, the jealous South Americans hindered the exportation of seeds and plants as much as possible The thrifty Dutch, though not actually the first to attempt the transportation of specimens, were apparently the first to succeed in taking them safely to the Old World In 1853 the Dutch government commissioned the botanist Hasskarl to collect cinchona plants and seeds for use in starting plantations in Java In 1866 the Dutch obtained from Charles Ledger, an Englishman long resident in South America, half of his collection of seeds of the valuable species since called after him *Cinchona ledgeriana* Collections for the cinchona plantations in India were made by Clements Markham in 1860, while half of Ledger's collection was purchased in 1866 by an Indian planter Both in India and in Java the cultivation of cinchona has proved a success, and the richness of the bark in alkaloids has been increased under cultivation and by selection of stock The U S pharmacopeial requirement is for not less than 5 per cent of total alkaloids, but good bark may yield a much higher percentage The effort of growers in late years has been to raise the quinin content rather than that of total alkaloids (Dispensatory of the U S A., article on cinchona rubra, p 344)

India is said to consume all or practically all the cinchona raised in that country (Roeder, George Tropenpflanzen, 1909, xiii, 473, quoted in Digest of Comments on the Pharmacopeia) The bulk of the world's supply of cinchona now appears to come from Java (Kraemer, Henry Scientific and Applied Pharmacognosy, 1915, p 738), though a comparatively small amount is still imported from South America, and some is now produced in Ceylon and Africa The South American plantations are said to have proved unsuccessful commercially, largely because the expense of transportation (on the backs of men over the mountains) makes competition with eastern cinchona impossible (National Standard Dispensatory, article on cinchona, p 448) The cinchona planter of Java inclines to take advantage of the market, which he now practically controls, and the rise in the price of quinin, which, as mentioned earlier, began before the present war, may be due in some degree to this circumstance

An Examination of Prisoners at Joliet Penitentiary

A preliminary report of a psychologic and psychiatric study of prisoners at Joliet Penitentiary, made by Drs H Douglas Singer and George Ordahl, appears in the *Institution Quarterly* Under present conditions, all convicts at the penitentiary are treated alike and associate with each other at haphazard It was realized that if the institution were to fulfil its true purpose, that of protecting society those persons capable of improvement should be singled out, kept segregated from the hopelessly antisocial convicts, and educated for a return to normal social life. While this purpose cannot be completely realized without universal application of the indeterminate sentence it was felt that something could be accomplished under the present system

It was impossible, in the time available, to examine all of the inmates of the penitentiary Fifty male prisoners were therefore chosen, in a manner intended to secure four representations of different types for study by Drs Singer and Ordahl. Fifty-one of the fifty-two female prisoners were studied by Mrs George Ordahl

The actual ages of the male prisoners ranged from 16 to 74, the average was 30 The mental ages by the Binet-Simon tests ranged from 6 to 16, the average mental age of the entire number was 11 2 Only seventeen prisoners tested above 12 years, fourteen were found to be feebleminded (below 10 years) The actual ages of the female prisoners ranged from 19 to 60, the average was 34 The mental ages by the Binet-Simon test ranged from 7 to 15, the average was 11 8 Fifteen of the female prisoners responded to the tests above the age of 12, five were feebleminded, or below 10 years

The investigators also grouped the prisoners in accordance with their fitness to become members of society as (1) criminals by accident, of adult and subnormal intelligence, (2) borderline cases, (3) antisocial persons, of adult or subnormal intelligence and (4) insane persons 1 The group of criminals by accident (those capable, if normal in intelligence of being educated for return to a useful and self-supporting life in society) included 16 normally intelligent and 15 feebleminded males, and 16 normally intelligent and 5 feebleminded females 2 The borderline group (persons apparently capable of improvement in spite of the presence of certain ominous traits) consisted of 6 males and 27 females 3 The group of persons regarded as absolutely unfit by Nature for life in society or commingling with the more hopeful prisoners included 13 males and 1 female 4 While the insane group is necessarily small, one case was studied in which crime was judged to be the result of definite delusions still present and active after detention for one year

The report emphasizes certain points which require remedy 1 The information concerning convicts available for the use of the board of pardons is so scanty and unsatisfactory that some prisoners are released when entirely unready for freedom and thus are given an opportunity to committe fresh crime, while other prisoners deserving of probation and liable to be harmed by prison conditions are detained 2 The selection of occupation for convicts seems to be based more on the needs of the prison departments than on the requirements of the individual to be trained 3 Recidivism, while most frequent among antisocial persons, is not limited to them It is especially emphasized that antisocial persons should be recognized, segregated to prevent their influence on persons capable of improvement, and, if their sentence permits of their detention, should not be permitted to leave

---

Book Notices

Principles of General Physiology By William Maddock Bayliss, M A, D Sc, F R.S, Professor of General Physiology in University College, London Cloth Price, $6 net Pp 850, with 259 illustrations New York Longmans, Green & Co, 1915

According to the author, this book is not an applied physiology, but rather an abstract physiology, presenting facts not found except in original papers or monographs, many of them not biologic, the knowledge of which is of fundamental importance in understanding the mechanism of living protoplasm

The book is both general and elementary, in that it discusses the importance of the following phenomena in an elementary and general way, each of the subjects given comprising a chapter in the book protoplasm, energetics, surface action, colloidal state, permeability of membranes and the properties of the surface of cells, osmotic pressure, electrolytes and their action, water, its properties and functions, catalysis and enzymes, oxidation and reduction, tonus, electrical changes in tissues, excitation and inhibition, contractile tissues, receptor organs and action of light This type of subject-matter receives only scant treatment or passing reference in most books The remaining chapters deal with subjects more commonly and extensively treated in the usual texts, such as nutrition, secretion, digestion, reflex action, nervous system, peripheral and central, respiration and the circulation of the blood The book ends with a chapter on hormones, drugs and toxins in which small, entirely inadequate paragraph references are made to the highly important glands of internal secretion Each chapter ends with a summary followed by references to important literature Besides the usual illustrations, there are scattered appropriately throughout the text portraits of the men whose striking discoveries have been of such fundamental importance in advancing physiology and its allied sciences, as Claude Bernard, Descartes, Emil Fischer, Graham, van't Hoff, Leeuwenhoek, Priestley, Ludwig, Ostwald, Ehrlich, Lavoisier, Pfeffer, Helmholtz, Pawlow and Harvey This feature will please all who love the biologic sciences and who, therefore, take a personal interest in the men associated with their history and development

The book might be recommended most highly for no other reason than that there is no book in the English language which contains a similar extensive and scholarly discussion of those processes, mentioned by title above, references to which are being made more and more at the present day, because their combined manifestation in a physical and chemical system constitutes, perhaps, life and living phenomena Should the text appear at times to be a loose compilation of data, every biologist will, nevertheless, be grateful to the author for the facts and the splendid bibliography made instantly accessible to him for his own further study and particular problems The aim of the book was high and the task was difficult, the result is so gratifying that any deficiencies appear negligible when the work is viewed as a whole

Diseases of the Nose and Throat By Algernon Coolidge, A B, M D, Professor of Laryngology in Harvard Medical School Cloth Price $1 50 net Pp 360, with illustrations Philadelphia W B Saunders Company, 1915

This is a small volume into which the author has attempted to compress the established facts and authenticated theories regarding the methods of examination, and the anatomy and physiology, of the nose, external and internal, and the pharynx and larynx, together with the etiology, pathology symptoms, signs, diagnosis and treatment of the long list of diseases to which these parts are liable He also includes chapters on diseases of the mouth and tongue, on diphther a, scarlet fever, measles, etc, and on bronchoscopy and esophagoscopy He appears to have attempted a little too much for the space occupied The book is intended as a manual for students and practitioners, and its brevity is one of its chief virtues As the author remarks, there are many things that can be learned only by clinical experience, but also much that is overlooked if this practical work is not accompanied by a reasonable amount of didactic study On this ground the book is of special value for undergraduates, because they have so little time in which to master the enormous volume of medical science with which they are expected to be familiar when turned out as full-fledged practitioners It would be much better if, aside from the fundamental sciences, the whole subject of medicine were taught from brief textbooks which should contain the essential facts This method should be combined with personal education of all the senses, and didactic and clinical instruction by competent teachers On this account we can specially commend this work to undergraduates, for it contains as much information on these subjects as they will be able to grasp and assimilate

Chemical Constitution and Physiological Action By Prof Dr Leopold Spiegel Translated with Additions from the German by C Luedeking, Ph D, and A C Boylston, A M Cloth Price, $1 25 net Pp 155 New York D Van Nostrand Company, 1915

Those who do not yet appreciate that our knowledge of the effects of chemical agents on animal organisms is no longer as it was primitively, largely a matter of mere haphazard discovery, will find in this little volume much fascinating instruction Our knowledge, not only of the influence of the nucleus of structure of an organic compound on its physiologic action, but also of the influence of constitution, that is, the nature and number of the constituent radicals and the grouping of these radicals, is increasing There is also a collection of data which furnishes us with an insight into the relation between the physiologic action of an inorganic compound and its component ions This knowledge, considered in connection with what is known about the composition and dynamics of cell substance and also, at times, in connection with certain physicochemical phenomena, enables us to predict with fair assurance the pharmacologic action of many compounds of which we know the structure From this account of the subject-matter of this work, it may readily be surmised that such knowledge has been utilized by experimental therapeutists and seized on by inventors of chemical therapeutic agents, but it also seems obvious that, before therapy can have become thoroughly rationalized, such knowledge must also become a part of the equipment of a prescribing physician While a treatise on this phase of medical science is hardly a novelty, this volume is welcomed, because the scope and manner of treatment of the subject-matter makes it of especial service as an introduction to the subject for those who have not yet become conversant with it, or for those whose acquaintance with it is not comprehensive It is all easily intelligible to any one with the average present day medical student's knowledge of chemistry

Convenant Against Use of Property for "Business" Not Violated by Physicians

(Iselin et al vs Flynn (N Y), 154 N Y Supp 135)

The Supreme Court of New York, Special Term, New York County, says that when certain lots were sold each deed contained a covenant that whenever the lot should be built on there should be erected a first-class dwelling house of specified materials and dimensions, and that there should not be established or carried on certain enumerated uses, "or any kind of manufactory, trade or business whatsoever, and that the building and buildings erected on said lots shall be restricted to private dwellings" A number of physicians eminent in their profession took up residence in the street, and it was claimed that they in fact conducted business which had consequential effects on the neighborhood But it was not necessary to enter on an ethical discussion of the difference between a livelihood gained by the practice of a profession and that by a business vocation The law is practical It is not concerned with abstractions, but with the actual affairs of men, and it recognizes the distinction between the practice of a profession and the conduct of a mercantile business One is purely personal, depending on the skill or art of the individual The other may consist in ability to organize and manage a shop or exchange where commodities are bought or sold Neither the spirit nor the letter of the restrictive covenant in this case intended or expressed prohibition of the practice of a profession, nor can sophistry pervert the real intent and plain meaning of the word "business" to include "profession"

Osteopaths Not Authorized to Practice Medicine

(State vs Dodd (Mont), 149 Pac R 481)

The Supreme Court of Montana affirms an order denying the defendant a new trial after his conviction of practicing medicine without having first obtained a certificate from the State Board of Medical Examiners The court says that the principal contention made was that the statute regulating the practice of medicine in Montana is unconstitutional Section 1591 provides that every person practicing medicine or surgery without such certificate shall be guilty of a misdemeanor, defines 'practicing medicine or surgery," and contains this proviso "Nothing in this section shall be construed to restrain or restrict any legally licensed osteopath practitioner under the laws of this state" It was insisted that the effect of this section, with the proviso quoted, is to deny to every person, except osteopaths, the right to practice medicine or surgery in Montana without a certificate from the State Board of Medical Examiners, and that in excepting licensed osteopaths from the operation of its provisions, those persons thus favored are free to engage in the practice of medicine or surgery without having to submit to the ordeal of an examination and without having the certificate required of every other one who seeks to engage in the like practice. But, in assuming that Section 1591 permits an osteopath to practice medicine without a certificate from the State Board of Medical Examiners, counsel for the defendant erred, and with the fall of this, his fundamental premise, went his entire argument. When the proviso was inserted in what is now Section 1591, the legislature understood that the practice of osteopathy (a) did not comprehend the practice of medicine or surgery, and (b) that it was already regulated and controlled by appropriate statutes enacted pursuant to the police power of the state The only effect, then, of this legislation, has been to classify all those engaged in the healing art into two classes (1) Physicians and surgeons, or those engaged in the practice of medicine or surgery, and (2) osteopaths, or those devoted to the practice by osteopathy In the absence of anything appearing to the contrary on the face of the statute, the classification made by the legislature will be presumed reasonable. Nor was there any suggestion in this case that such a classification as was undertaken above is unreasonable The proviso in Section 1591 is a harmless piece of legislation It did not affect the status of osteopathic practitioners in the least They were confined thereafter, as theretofore, to the practice of osteopathy and forbidden to practice medicine or surgery without the certificate from the State Board of Medical Examiners required of every one who seeks to engage in such practice Neither has the legislature, by enacting Section 1605 of the Revised Statutes, recognized osteopathy as including, or included within, the practice of medicine That section does not authorize an osteopath to "treat, cure, alleviate any disease of the mind or body by any treatment," as counsel for the defendant contended in his brief The language of the section cannot be tortured to convey such meaning Within the entire scope of his practice, the osteopath is confined to treatment by the use of the hands or mechanical appliances

Liability of Relatives for Medical Services and Hospital Care

(Tryon vs Town of Moyer et al (Minn), 153 N W R 307)

The Supreme Court of Minnesota reverses orders sustaining the demurrers of Defendant Ernest Dornfeld to the complaint of the plaintiff in this case and to the complaint of the Benson Hospital Association in a case decided with this one The court says that this was an action for the reasonable value of medical and surgical services rendered by the plaintiff to one Rosie Dornfeld, a granddaughter of Ernest Dornfeld, and the other case was for services and care rendered to her by the association in its hospital It was stated that Rosie Dornfeld had been seriously injured, and that she and her parents were public charges on the town of Moyer, but that her grandfather was able, financially, to respond for the expenses of her care and attendance, but refused to pay therefor The question presented by the record was whether one who has furnished to a dependent relative medical care and treatment or hospital care and services in an emergency case, where there is an urgent requirement for both physician's services and hospital care, imperative and admitting of no delay, can recover from a relative, on whom rests the statutory duty to support such dependent relative, compensation for the reasonable value of such services, even though such services were rendered without the knowledge of the relative sought to be charged The court holds that he may The Minnesota statute provides that every poor person who for any reason is unable to earn a livelihood, shall be supported by his children, parents, brothers and sisters, grandchildren or grandparents, and relatives having sufficient ability shall be called on for such support in the order above named, etc The duty is created by the statute, and does not depend on contract It is a duty which devolves primarily on the relatives, it cannot be evaded or shifted on others Cases may arise in which notice to the relative may be required, but the court was not dealing with such a case. It sufficiently appeared from the complaint that Rosie Dornfeld was very seriously injured, that she required the promptest attention, that it was imperatively necessary to operate immediately in order to save the child's life It appeared that everything was done for the child that could have been done by Defendant Dornfeld himself, and that the services rendered were reasonably proper and necessary Under these circumstances, it could not be successfully contended that the duty rested on the plaintiffs to give notice to the defendant Dornfeld before doing that which it was imperatively necessary should be done in order to save the child's life There was a legal duty on the part of the Defendant Dornfeld to support and care for his granddaughter An emergency arose The necessity for medical, surgical and hospital services was immediate, urgent and imperative The plaintiffs having performed the services it followed that the defendant Dornfeld was primarily liable to pay for the reasonable value of such services, at least until such time as he himself could act in the premises The complaint in both cases stated a cause of action against the defendant Dornfeld

Joint Meeting, held at Philadelphia, Nov 9, 1915

Dr William N Bradley, Philadelphia, in the Chair

Lobar Pneumonia The Correlation of Its Symptoms and Physical Signs with the Findings of the Roentgen Ray

Dr Howard H Mason, New York During the past two years, at least one roentgenogram has been taken in each case of lobar pneumonia on the children's service at the Presbyterian Hospital In those cases showing a shadow, but in which bronchial voice and breathing were not heard, roentgenograms were made at varying intervals The purpose of these examinations was to ascertain whether or not the consolidation as evidenced by this shadow passes through any regular development, and if so, whether the different stages of its progress can be correlated with the development of certain physical signs Thirty-seven cases of lobar pneumonia were studied Each case showed a definite shadow The shadow was always so placed that it touched the pleura at some point. The early shadows were triangular, with their bases on the pleura and their apices separated from the region of the root by normal lung In their later development the shadows extended in size and became uniform from the periphery to the root of the lung When the shadow involved this entire stretch, bronchial voice and breathing were present, but not otherwise It is believed that the inference is justified that the dimensions of the shadows correspond to the extension of consolidation

Tuberculosis in Infancy

Dr Charles Hunter Dunn, Boston The importance of tuberculosis as a cause of death in the first two years of life is shown by the fact that in a series of sixty-two successive necropsies, tuberculosis was found in twenty-five, was considered the direct cause in twenty-three cases and the contributing cause in the other two Extremely divergent views are held concerning the source of infection and its portal of entry into the body One set of writers believes that milk infected with the bovine type of bacillus is the most common cause of the disease in infancy, and the intestinal tract or the tonsils the most common portal of entry Other writers believe the human type of bacillus to be the most common cause, and the lungs the portal of entry The two most important forms of evidence bearing on this question are (1) that derived from bacteriologic study of bacilli obtained from infants by culture or animal inoculation, and (2) that derived from a careful study of the lesions found postmortem Postmortem findings show a greater frequency of involvement of the peribronchial and mediastinal lymph nodes than of the mesenteric Advocates of milk infection try to explain this on the theory that the bovine bacillus can pass through the intestinal mucous membrane and through the mesenteric lymph nodes without causing a lesion, locating in the lymph nodes of the chest as the point of minimum resistance This theory I believe to be untenable. The contradictory evidence on the source of infection and portal of entry can be explained only on the ground of a variation according to locality Such variation is probably largely dependent on the character of milk supplies and the frequency of tuberculous disease in cattle in various parts of the world I believe that infants can be infected either with human bacilli, usually entering through the lungs, or with bovine bacilli, usually entering through the intestine The most generally accepted view is that tuberculous infection shows the primary lesion in the lymph nodes In my studies at the Infants' Hospital, a primary incision was actually found at the portal of entry in twenty-two of the twenty-five postmortems I have inclined, therefore, to believe Ghon that it is more probable that when a primary lesion is not found at the portal of entry it is overlooked The primary lesion was found in the lung in twenty cases, and in the intestine in two Adding to the twenty cases, the three in which the only chronic lesions were found in bronchial lymph nodes, we have a ratio of twenty-three cases of infection through the lung to two cases of infection through the intestine Tuberculous ulceration of the intestinal mucous membrane was found in seven cases besides the two in which the lesion was considered primary I believe it to be a probable conclusion that these tuberculous ulcerations of the intestines are secondary to swallowed tuberculous material coughed up from the softening of the primary lesion These seven cases with secondary tuberculous ulceration of the intestine were identical with the seven cases in which the mesenteric lymph nodes were involved in addition to the bronchial lymph nodes I believe my findings to be against the view of the ability of the tubercle bacillus to pass through the intestinal mucosa without leaving traces of its progress in the form of a definite lesion In the series the diagnosis of tuberculosis was made in twenty-three out of twenty-five cases, but these were all seen in the last stages of the disease Three important points besides tuberculous meningitis or tuberculous peritonitis on which the diagnosis of tuberculosis in infancy is based are (1) physical signs suggesting tuberculosis in the chest, (2) tuberculin reaction, and (3) Roentgen-ray examination of the chest.

MEDICAL SOCIETY OF VIRGINIA

Annual Meeting, held at Richmond, Oct 26-29, 1915

Custodial Care of the Feebleminded

Dr L T Royster, Norfolk "Responsibility" is a relative term, it depends on the mental rather than on the chronologic age. A liberal percentage of these classes are not responsible A method has been found to test them, this is the Binet test. They have a lowered resistance to immoral influences Physical causes may be back of it hookworm, etc A large percentage of prostitutes are not over 12 years of age mentally Two per cent. of schoolchildren really belong in the feebleminded class Defectives almost always breed true There are three main lines on which to work (1) prevention of propagation, (2) state control to care for the defectives, (3) relief of indigent parents We must detect this early to apply treatment

Diagnostic Value of Psychanalysis in Nervous Diseases

Dr J Allison Hodges, Richmond Diagnosis by dreams is of interest to doctors if there is any truth in it Dreams are stories of wishes Mental life is conscious and subconscious or unconscious The difficulty is in the interpretation, many interpretations are farcical For the average physician it is impracticable How much of the benefit is due to suggestion from the doctor? If we spend more time getting into the inner thoughts of the patient, we shall not have to rely on dreams

DISCUSSION

Dr A. L Tynes, Staunton We have been laying too much stress on the pathology of anatomy, we should put more on the pathology of physiology I do not believe that the analysis of dreams is necessary to accurate results Careful history taking is very important In the more complex neuroses we are treading on dangerous ground, we should refer these patients to the neurologist

Dr. Tom A Williams, Washington, D C. We should attack the underlying cause, not the hysterical paralysis, for example Relieving this does not cure the patient, the causremains Psychanalysis is as old as philosophy, it means determining the trend of the patient's thoughts

DISEASES OF THE BILIARY TRACT

Etiology and Pathology

Dr. S B Moon, Richmond One attack predisposes to another It becomes a habit The germs enter through the mucosa and set up a focal necrosis Most of the common bacteria of suppuration are concerned, the colon bacteria is perhaps the most frequent. The bile is altered in character Gallstones are infrequently formed anywhere except in the gallbladder Their formation is slow, occupying from two to five months Cholesterin is always present, and may be the sole ingredient Crystalloid and colloid substances are always in the bile, a disturbance of equilibrium between these two results in precipitation of one or the other Enzymes may be the disturbing factor set free in the bile Streptococci are not concerned in gallstones Gallstones are a fruitful cause of cancer of the gallbladder

Symptoms and Diagnosis

Dr. Hugh H Trout, Roanoke The past history should be studied carefully History of previous attacks assists In our series of 196 cases they were most frequent between 30 and 40 years, the youngest patient was 4 and the oldest 76 The most constant symptom was indigestion which occurred in 112 cases It is fortunate that most diseases that produce pain in this region are surgical, a dull aching at first. Pain radiating to the right shoulder in our series was of little value Sharp pain of short duration, from two to five hours, but dull ache persists Spasm of the right rectus muscle persists only during the acute attack Elevation of temperature was most uncertain Blood count was of great value, in diagnosis and prognosis Agglutination time should always be noted. Waiting for jaundice is most uncertain

Medical Treatment

Dr. Hugh McGuire, Alexandria At first food should be limited to milk and cereal, and alcohol prohibited. The patient has a repugnance to fats Proper laxatives are most important, and drastic purgatives only still further irritate the mucous membrane Broken doses of calomel should be tried Zinc oxid starch and camphor are useful In gastric catarrh lavage should be used Treatment for relief of acute symptoms must be used before the exact condition can be found out. The suppurative form is amenable only to surgery In the prophylaxis of cholecystitis, hexamethylenamin should be administered throughout typhoid Olive oil is of no benefit Hot compresses should be used, and the patient starved for the first twenty-four hours

Surgical Treatment

Dr. Lomax Gwathmey, Norfolk I am glad to see that surgeons and medical men are close together on this question If the case is seen early, operate, if the inflammation is waning, wait

Discussion on Diseases of the Biliary Tract

Dr. Hugh Taylor, Richmond One type of bile tract infection is an attenuated infection The ampulla opens on the mucous membrane of the duodenum by so small an opening that we can scarcely see it, yet it drains a big tract The key to the situation is not the removal of the stones, but the drainage of this vast tract.

One Hundred Cases of Heart Disease in the Negro

Dr. Charles R Grandy, Norfolk I was struck with the relative infrequency of rheumatism as a cause in the aortic cases and the large proportion of aortic cases, 56 as against 36 per cent. of mitral cases Only five aortic cases had rheumatism as the cause. Hard work on the docks is an infrequent cause of heart disease the natural cardiac strength of the negro enabling him to continue work at very hard labor A preacher, aged 65, had a systolic blood pressure of 280, with diastolic of 180 and not symptoms enough to make him return to the dispensary One negro with a pressure of 210 still pushes a truck on the docks Normal blood pressure in adults is from 110 to 140, without regard to age, I have found persons over 80 with a pressure of 130 I would not make a diagnosis of aortic regurgitation without a high pulse pressure

DISCUSSION

Dr Douglas Vanderhoof, Richmond Rheumatic or streptococcic cases are extremely amenable to treatment if seen early Removal of the tonsils must always be considered in these cases

Dr J W Preston, Roanoke The polygraph and the Wassermann test are of great value in the study of heart cases The heart carries the load till it cannot any longer, then we get an arrhythmia We know that as long as the heart is doing well it is better not to try to bring down the blood pressure We can save a patient's life often, by treatment when failure begins

Dr. P S Roy Washington, D C I would call attention to some points in diagnosis If the patient has great shortness of breath spits blood, and has a red face, we feel that we have a mitral lesion These patients do not often spit blood in the aortic cases, and have dyspnea late if at all If they have regular beat, and over 120, we know the remedy is digitalis, if it does not respond to 40 drops, results will be obtained from 80 drops The blood pressure before and after exercise should be taken If the heart is doing well, it should go up 10 or 15 points, if the heart is not doing well, it will go down Dropsy or enlargement of the liver, hydrothorax etc., is more liable to occur in mitral than in aortic disease

Dr. A L Tynes, Staunton Fibrillation of pulse is a symptom of grave prognostic significance McKensie reports a series of cases, but not as large as White's He found that not a single patient in whom this was observed was living after two years

Dr W E. Anderson, Farmville We are attaching too much importance to blood pressure measurement. The heart stands as much use as any organ, and I think as much abuse as well

Dr. P S Roy Without the presence of extrasystole, the alternating pulse is the last cry of a dying heart

Posthospital Treatment

Dr. Stuart McGuire Richmond The surgical operation never cures a patient, it only puts him in the way to get well It often takes months and even years for the patient to get back to his normal The question at once presents itself whether the surgeon or the family doctor should be responsible for him during this time The best results are obtained by intelligent cooperation between the patient the family doctor and the surgeon The patient is sometimes so impressed by the hospital regimen that he is inclined to look back to the surgeon rather than forward to the physician Questions as to clothing, diet, whether or not to wear corsets, abdominal binders, baths, douches, the resumption of sexual relations etc tax the physician's knowledge and common sense In the first place, all the facts of the operation and the subsequent convalescence should be written to the physician by the surgeon I put the directions in writing so as not to tax the intelligence or understanding of the patient Ten or twelve forms may be kept on hand that will cover most cases in which operations are performed in the general hospital, and revised for occasional cases One or more of these forms should be sent to the physician for the patient's instruction.

Mucous Colitis

Dr. John W Preston, Roanoke There are two erroneous impressions about this malady that it is rare, and that the treatment is rebellious As to frequency two thirds of all young adults are afflicted some time. Twenty-three patients with it have been under my care in the last five years The sympathetic and the vagus constitute the autonomic nervous system The vagus produces a spasmodic action in the intestine, and the sympathetic the reverse. This gives an idea of the value of belladonna and epinephrin

THE STATE VERSUS TUBERCULOSIS

Dispensaries in the Fight Against Tuberculosis

Dr Louis Hamman, Baltimore It is impossible for me to contemplate a method of combating tuberculosis that does not give a prominent place to the dispensary The first task of the dispensary is getting patients, but this is the easiest The nurse is most important in getting the confidence of families They must have more considerate treatment than in the usual dispensary The second important thing is early diagnosis Early cases must be recognized Experience is necessary to reach success Third is the plan of treatment The importance of this is great to the patient I do not feel that it is the function of the dispensary to treat great numbers The nurse is just as important in giving instruction as is the doctor So many things follow tuberculosis that a social service department is always necessary to solve the economic difficulties If the staff is large enough it may make clinical study of the cases presented, and so the dispensary may serve as a center where new facts may be ascertained The schools are deficient in the instruction about the treatment and diagnosis of tuberculosis We have eighteen municipal nurses in Baltimore.

The Visiting Nurse in the Fight Against Tuberculosis

Dr David R. Lyman, Gaylord Farm Sanatorium, Conn If I were restricted to any one of the four agencies in treating tuberculosis, namely, sanatoriums, dispensaries, advanced hospitals and the visiting nurse, I would unhesitatingly take the visiting nurse, because the others would follow as the night the day All four are needed New York nurses have found an average of five cases for every one registered The nurse gets to know the people, and if she is visiting one family she is very likely to hear it if another family on that street has some one with a chronic cough In ten years, 1,122 discharged patients earned $1,339,000 I find that patients do better at their old occupations and do better indoors than out In common with other states, with your nurseries, your laundries and your kitchens in the hands of a race whose death rate from tuberculosis is treble your own, where should your campaign logically begin?

Discussion on the State Versus Tuberculosis

Dr Stephen Harnsberger, Catletts Tuberculosis is found largely among the poor, and the wage earners So it should be largely a state or a governmental matter Environment is of primary concern in the fight against tuberculosis Eradication is largely a matter of abolishing poverty

Dr. John J Lloyd, Catawba Sanatorium, Va We have a sanatorium of 168 beds which I believe will be sufficient to care for the incipient cases for several years to come, and $192,000 earned by discharged patients is a good percentage on the amount invested by the state Too many come with the idea that they will be well in one, two or three months The patient is too apt to think that if he visits the doctor once a week, he can do as he pleases the rest of the time The nurse who has had tuberculosis makes the best nurse The negro problem is the biggest and the hardest one to handle

Dr. W A Plecker, Richmond The worst—the number of deaths from this disease—has not been told They are erroneously reported The colored people realize that it is not a good thing to have it known that they have tuberculosis I think probably there were 4,000 deaths If in our power, we are going to make the death rate from tuberculosis *seem* higher by getting more accurate figures

Dr. P S Schenck, Norfolk We listen to these addresses by specialists, and we are filled with enthusiasm, we go home, and we do nothing We should go at fundamentals, namely, money and authority—authority to take the tuberculous patient out of his family, and place him where he would no longer be a menace There are only five states in which the death rate from tuberculosis is higher than in Virginia

Dr R W Brown, Roanoke I have been impressed with the fact that while early diagnosis is important, yet the majority of patients who come to me as preliminary examiner for Catawba Sanatorium are too far advanced to enter the sanatorium I have lost some of the best patients in my clientele by making a diagnosis of early tuberculosis Another fact is that we must have some place where the advanced patients can get treatment.

National Board of Examiners

Dr. L A LaGarde, Washington, D C I am here tonight at the bidding of Dr Gorgas, in a matter in which he is much interested Everything is tending toward military preparedness, these days, so that if a crisis comes we shall not break down as we did in the medical department in 1898 The army has no difficulty in getting anything it asks of Congress at present, but what we are asking for now Congress cannot give We want men to assist us in time of war We want to prepare the medical men before the crisis In foreign countries now there is not a medical man who is not in some way or other connected with the army medical corps The 0 7 per cent which we have is not a drop in the bucket if a crisis should arise We have among other organizations the Red Cross We have of course also the National Guard Medical Corps But that would not be enough We formed the Medical Reserve Corps some time ago, but it is not yet to our satisfaction. Dr Rodman is the father of a movement to establish a central board for examination of physicians, so that they may practice their profession in any state, territory or possession of the United States Dr Gorgas says he will take the licentiate of this board without further examination. We can give training through summer camps and through correspondence Many associations have adopted resolutions favoring cooperation in this matter (Note A resolution favorable to this was passed)

Sanatoriums in the Fight Against Tuberculosis

Dr. Lawrason Brown, Saranac Lake N Y In the early eighties, the sanatorium idea reached America, Trudeau and Bowditch founded the institutions Today we know that some patients pass through no incipient stage but leap from the doubtful to the advanced stage I believe that tuberculosis is curable, but I hold that permanent arrest is the most frequent termination in the majority The remainder of the life of the sanatorium patient must be a "sanatorium extension course" He must apply and change the knowledge until knowledge is replaced by wisdom which is assimilated knowledge The sanatorium must be given credit for starting the crusade Later the public began to demand that an early diagnosis be made A great factor in enlightenment is the influence of patients who have been educated at sanatoriums Hard work, questionable food and rest at night in a room that cannot be ventilated means defeat for many Every worker has heard of the "unteachable consumptive" He struggles to support his family and grows worse, bitterness comes and carelessness, the tubercle bacillus is planted in his children, here the "night sanatorium" may be the means of saving Thirteen states have passed laws authorizing the erection of county tuberculosis hospitals

Control of the Poor Consumptive

Dr. Charles L Minor, Asheville, N C I speak of the poorer class of workmen and workwomen, and of our hosts of negroes whose dirtiness and ignorance is rivaled by our foreign immigrants, their tenements characterized by dirt, darkness, dampness and lack of fresh air, the dirty children playing on the dirtier floor on which the sick members expectorate indiscriminately Do you think you or your children could stay well under such conditions, forced to eat the horribly cooked food the tired, ignorant, overworked wife prepares? Could you educate your children into healthy and useful citizens in such surroundings—sickness, no hygiene, poor food, bad examples and bad companions all around them? Leave this poor man where he is and he will surely die, but he will also drag down his family and often his neighbors, remove him to a place where he can get proper care till he dies, disinfect his tenement, watch over his children, and you will nip in the bud a focus of infection whose evil possibilities are hard to overestimate You are forced to the only satisfactory solution of this problem, to give your health department police power to remove him from his home, and place him in a specially constructed hospital Here rendered harmless to his friends and his community by skilful care and thorough sputum disposal, visited at intervals by his family, he can pass his last days in comfort, no longer a menace. Liberty is conditioned on its not bringing harm to other citizens When our legislators recognize the importance of this, they will evolve laws to meet the situation If 3,500 Virginians die yearly from tuberculosis, each furnishing a focus of infection, the number is certainly large enough to justify the expense I would say most emphatically that it is utterly impossible to care for these poor invalids in their homes Those who know the habits of our poor, and especially of our negro poor, will have no illusions on the subject The buildings may be inexpensive, the administration must be moderate

---

NATIONAL ASSOCIATION FOR THE STUDY OF PELLAGRA

Third Triennial Meeting held at Columbia S C Oct 21 22 1915

(Concluded from page 2117)

The Etiology of Pellagra, with Especial Consideration of the Phenomena of Sensitization to Maize and Sugar Cane Products

Dr. Roy Blosser, Atlanta Ga. I do not blame granulated sugar or carbohydrates as a class with having anything to do with the production of pellagra I claim that certain products of sugar cane contain an active poison and that all that is necessary for the development of the disease is consumption of a sufficient quantity of these poisons I no more believe that the consumption of meat and proteins can prevent pellagra than that it can prevent the development of alcoholism in the regular drinker though the moderate consumption of proteins is advantageous in the treatment of pellagra My claims as to the production of pellagra by partially refined sugar cane are based on the effect of the experimental administration of these products to dogs, also to the results obtained in the treatment of from 100 to 150 cases of pellagra, seventy-two of which have been under observation more than a year with no relapses The treatment has been strict abstinence from cane sugar and maize products Pellagra is a disease of improper diet, it constantly presents marked gastro-intestinal symptoms which antedate by many months or years the condition recognized as pellagra Change in diet is admitted to be necessary in treatment. In some cases the extreme, not moderate, consumption of maize is the main factor in its production There is a close resemblance between the effect of sugar cane and alcohol, the difference being one of degree. Individuals consuming continually large quantities of sugar cane products become sensitized to them In advanced and chronic forms of pellagra sugar cane products cause burning of the tongue esophagus and stomach palpitation of the heart and nervousness Notwithstanding the unpleasant symptoms the habitue craves the stimulation of the sweets One who has become sensitized to maize will react to sugar cane and vice versa The reaction is more marked in warm weather than in cold Recent investigators have explained this reaction as a form of anaphylaxis

The Problem of Spoiled Corn

Mr. E. J Watson Commissioner of Agriculture, Columbia, S C. The Southern States have been made the great dumping ground for impure corn products Last year in South Carolina 108 out of 240 shipments of corn meal were made of spoiled corn unfit for a hog much less for human beings This corn was from other states Dangerous meal cannot be detected by inspection, as is shown by the samples exhibited Over 40 per cent. of the corn meal shipped into the state in 1914 was unfit for any purpose and it was either confiscated and destroyed, or when it was just above the minimum standard of safety we have permitted it to be shipped back. What effect meal from spoiled corn has had on the health conditions I do not know The spoiling of the corn is due to the miserable system of shocking corn in the fields The foundation of the whole trouble is the moisture which comes on account of the upturning of the ear in the shocks which allows the development of poisonous fungi Meal from spoiled corn is not the only injurious fungi

Etiology of Pellagra

Dr George C Mizell, Atlanta, Ga A working hypothesis of the etiology of pellagra which appears to harmonize all disputed points is this The one essential primary cause of pellagra is the consumption of excessive amounts of fat of the cottonseed oil group, and the storing of these oils, and their oxidation products in the body The condition which facilitates the storing of these fatty compounds we will term the secondary cause of pellagra The secondary cause is any systemic intoxication [After developing his hypothesis and giving his observations in a number of institutional and other cases, Dr Mizell reached the following conclusions] In every region in which pellagra exists, oils of the cottonseed oil group are consumed. Where these oils are excluded from the diet of the individual or the institution, pellagra ceases to exist. The cottonseed group of oils is the only common constituent of the food of pellagrins of this country, it is of undetermined wholesomeness, and it is the only food that corresponds to the incidence of pellagra in the United States The common constituent of these oils which differs from constituents of known wholesome oils is linolein, therefore it follows that linolein is the cause of pellagra. There are many conditions such as climate, local infectious diseases, constitutional diseases, conditions of skin, conditions of the gastro-intestinal tract and habits of individuals in selecting food each separately and collectively which play a part in the incidence and progress of the disease, but the essential cause is consumption of excessive quantities of linolein

DISCUSSION ON ETIOLOGY OF PELLAGRA

Dr H F Harris Atlanta, Ga The idea that oils are associated with pellagra is very old, like everything else connected with the subject There are really no actual facts as introduced that would go to show there is any truth in the idea In the southern part of the country, where pellagra does not exist, they eat olive oil, but it is in the northern part that it occurs They have practically no other food except maize It would seem to me the people who live largely on oils would suffer if there were any truth in this hypothesis, for example, the Eskimo and the people of southern Italy, who eat a great deal of oily substances One point in regard to the statement made by Commissioner Watson That rotten corn is harmless is a curious doctrine. It is well known that maize, in its early stage, becomes highly acid but at a later time the bacteria convert the albuminous portions until we get a product that is not poisonous

Dr. Mosby Durham, N C. Dr Mizell is advancing a very ingenious theory I have known it for some years and have never been able to accept it. There is one thing I would like him to explain on his theory We see a mother who has pellagra and she prepares the food for the rest of the family, and the rest of the family take pellagra If it is a boarding house keeper, we do not see so much of this pellagra. I am convinced that pellagra is an infectious disease

Dr. Adam Hayne, Columbia S C. The doctrine that spoiled maize is the cause of pellagra in South Carolina has been absolutely refuted on the floor here by the commissioner of agriculture. He stated that there was no spoiled corn raised in South Carolina, that none was allowed to come into the state, and that it was turned back. Yet the fact remains that there have been 1 083 deaths in this state from that disease since January 1 of this year Now, if we are going to tell the people of this state that it is due to corn and corn products, we are going to tell them something that we cannot prove by the facts

Dr. Roy Blosser, Atlanta, Ga Dr Mizell does not claim that corn does not cause pellagra I think he claims it does, and advances his theory as another cause Some Italians do not eat corn, but some of them do, and it is up to some one to explain what causes pellagra when they do not eat any maize, and when maize is not imported into the country

Dr. Cosby Swanson, Atlanta, Ga If cottonseed oil is the cause of pellagra, why is it that we do not *see more* cases of pellagra in persons between 12 and 18 years of age? In patients suffering from pellagra there is *less* fat deposited in the skin, the sweat and sebaceous glands are not so active, skin is usually dry and hard, because of their inactivity

George C Mizell, Atlanta, Ga There is not one fact statistics that does not substantiate this hypothesis Dr is said, "As an evidence that this theory is not true, in Italy and in France where much olive oil is used, pellagra does not occur" Olive *oil is a nondrying oil* Cottonseed oil is a drying oil The Eskimos do not have pellagra because they do not eat *this sort of oil*, but blubber oil, which is entirely different Dr Harris stated, in his bulletin, "It has been definitely shown beyond *any* doubt *that* there is a poisonous substance in cottonseed, and that it has nothing whatever to do *with the oil*" I have data to show that it has not been *proved*

Goldberger says, "Pellagra is due to something that re eating or are not eating" He says, "They are eating cheap class of food, cheap carbohydrates, meats and fats (sow belly)" You cannot produce one patient with pellagra who eats fat derived from sow belly alone, in connection with other cheap nonfatty foods

Dr Siler wanted to know why negroes in one locality have pellagra to a greater extent than in another The negress may cook for the white people in the city She feeds her family from the white people's table, they get the same products that the white people are eating Let the negro alone and he will buy sow belly and use the grease for cooking, thus excluding drying fats Again local conditions may be a secondary factor in different localities

Dr J F Siler, Washington, D C Why is it that in people between the ages of 20 and 45, so many more cases occur among women than among men, in white *people* particularly? We have a tremendous number of cases among the females

Dr. George C Mizell, Atlanta, Ga It is due to the fact that mothers and other women of this age have more unstable health, 65 per cent of my gastro-intestinal cases are in mothers who have gastro-intestinal autointoxication and female disturbances, which are often the secondary causes in pellagra

In regard to Dr Swanson's question, children between 12 and 18 do not often have pellagra because that is the period of adolescence During that period they have a much more active sebaceous secretion which enables them to take care of large amounts of incompletely oxidized fatty waste products The skin does not dry so easily

Etiology of Pellagra in Children A Study of Two Hundred Cases in Orphanages

Dr H W Rice, Columbia, S C Of 200 cases of pellagra in children in orphanages, 182 occurred in a local institution in four epidemics [Data are given with reference to corn, and other dietary considerations, together with statistics regarding age, sex, coincident disease, immunity, etc, and the study is summarized as follows] The facts in a large percentage of our cases of pellagra in this orphanage strongly discredit a causative relation of corn The incidence of pellagra is much higher in children under 12 years of age The discoverable differences in the diet of the smaller and larger children seem inadequate to account for this age distribution Children are more than three times as liable to develop pellagra during the first year's residence in the orphanage as in any subsequent year There appears to be some relation between the amount of animal foods consumed and the spread of pellagra in orphanages The predisposing factors, age, sex, hereditary weakness, poor nutrition and coincident diseases, apparently were operative in this series of cases

DISCUSSION

Dr J F Siler, Washington, D C In connection with a study of another orphanage in this state which we made during the course of two years, it might be interesting to refer to two or three points that Dr Rice has brought out in his paper This institution had about 250 orphans, the ages ranging from 5 or 6 to about 18 The majority were females, and it was interesting to find, just as Dr Rice found, that about 75 per cent of the children developed pellagra in the first year of residence Two children, aged 5 and 6 years, were sent to the orphanage from Lancaster, Pa It is *improbable* that the disease existed prior to their admission Within six weeks after admission both of these children had pellagra The diet, you can call it incomplete, poorly balanced, or anything you may choose, was not a good one They had in this institution about forty cows, and the dairy supply of milk in 1914 was about 50 gallons per day A great deal of the milk was made up into butter and there was much buttermilk They had peas and beans frequently, and slaughtered *their own* beef twice a week, so that they sometimes had enough beef to last for four days during the week *In the fall* and winter they had a great deal of fresh pork, but the diet was not, *in* our opinion, a satisfactory one, and we recommended that they add milk and eggs and more fresh meat

I do not think beans and peas have anything essentially to do with the prevention of pellagra I do think, however, that beans and peas should enter extensively into the dietary of the people, and so far as we could determine in our field observations in this country and elsewhere, they do form a very conspicuous feature of the dietary where pellagra is endemic I was somewhat surprised in the fall of 1914 to see the papers of the South filled with the slogan, "To cure pellagra, eat beans, to prevent pellagra, plant beans and peas" I note that the slogan this year (1915) is, "Buy a cow" To this recommendation I most heartily subscribe Our *dietary* investigations lead me to doubt very seriously that beans and peas contain the hypothetic pellagra-preventing vitamins in any great amounts

Dr W J MacNeal, Washington, D C A thing of great *importance is the* age distribution of pellagra This is probably a matter of physical resistance of individuals at different ages It means simply the resistance to disease of all sorts, and follows that curve Of course it is not absolutely so, but there is that tendency to resistance of disease of all sorts During the period from 15 to 19 the death rate is low and the natural vitality greater than in other periods The recovery of these patients while continuing on the same diet is important These children come here, they take this deficient diet, which we may criticize as much as we will, without saying in exactly what respect it is *deficient* They show typical erythema, and subsequently recover and live three or four years without recurrence

Dr. Joseph Goldberger, Washington, D C The immunity to which Dr Rice calls attention, which apparently developed after one or two years of residence at the orphanage can be explained by the fact that after a year or two of institutional residence, the child reaches the age which admits it to the group having the better diet The fact that the difference in the diet of the younger and of the older children did not seem adequate to Dr Rice to explain the difference in the incidence of pellagra in the two groups should have no weight The important thing to remember is that a difference was discernible In the present state of our knowledge we have no way of telling whether a particular diet is adequate or inadequate The only way we can judge of that is by its physiologic effects that is, by trying it for a long enough time

Dr George C Mizell, Atlanta, Ga If diet is the cause of pellagra, there must have taken place in the diet of the American people some radical change Fifteen or twenty years ago people were just as particular in the selection of their diet as they are today Take into consideration the fact that in 1908 only 10 per cent of the people were eating cottonseed oil products In 1910, 48 per cent of the people were eating cottonseed oil products The consumption of cottonseed oil products jumped to 50,000,000 gallons in 1908

Dr H W Rice, Columbia, S C My personal opinion is that children should be fed more milk and not so much meat, but they should have more of both than the children of this orphanage have had Coincident disease as well as dissipation in adults no doubt plays a part in the etiology As to Dr Goldberger's point, that there was shown to be a difference in the diet in the older and younger children, I said that the slight difference did not seem adequate to account for the relative difference in the incidence of the disease in the respective groups Of course it can be only a matter of opinion in the present state of our knowledge of the subject

Comparison of Chemical Changes in Central Nervous Systems of Pellagrins and Animals Subjected to an Exclusive Vegetable Diet

Mathilde L. Koch and **Carl Voegtlin** Spartanburg, S C If pellagra is due to a dietary abnormality, as has been suggested by many students of the disease, it should be possible to reproduce in animals by dietary means some, if not all, of the pathologic changes which are observed in pellagra The present paper represents an abstract of one phase of this investigation, and can be summed up as follows The diet which seems to give rise to pellagra is made up largely of vegetable foods being rich in carbohydrates This diet, if fed continuously to healthy monkeys, rats, mice and other animals leads to symptoms and chemical and histologic changes in the organs very similar to those found in pellagra Although the explanation as to how this diet leads to pellagra is still lacking the observations made on our animals furnish valuable support to the dietary theory of this disease. These observations are particularly important when brought into connection with the extensive unsuccessful attempts to transmit the disease to animals by means of inoculation of material from pellagrins Both the diet used in these feeding experiments and that consumed by persons developing pellagra seem to be lacking in certain chemical substances contained in relatively large amounts in such animal foods as milk eggs and meat.

DISCUSSION

Dr. J F Siler Washington D C. It is extremely interesting that pellagra concurs with such remarkable rarity in nursing children We know from the literature of the subject that beriberi a deficiency disease is common in nursing infants If pellagra were a deficiency disease it seems to me that its age distribution, so far as nursing infants are concerned, would be similar to that in beriberi As a matter of fact it is hardly possible to have a more remarkable dissimilarity

Dr. Roy Blosser Atlanta, Ga I am sorry that Dr Voegtlin did not emphasize the pathologic conditions in the spinal cord The essential changes in pellagra of the spinal cord are in the upper part of the cord and distinguish them from the changes in other diseases, notably tabes I think corn syrup in the diet was mentioned That term, I think, ought to be eliminated because corn syrup is a mixture and it has a very high percentage of glucose which, so far as we know, is chemically pure That is the only place where the corn gets in so I think it would be much better if that term were eliminated but I do not know what term could be substituted in its place

Carl Voegtlin Spartanburg S C In regard to the comment of Dr Blosser it seems unnecessary to call attention to the great similarity of the photomicrographs of the spinal cord in our experimental animals with those obtained from pellagrins Anybody who has seen the work of Tuezek will be struck by the great resemblance of his illustrations with those presented today The corn syrup used at the Pellagra Hospital is not chemically pure glucose, it is made from corn starch

Differential Diagnosis of Skin Manifestations of Pellagra

Dr. Cosby Swanson Atlanta Ga The differential diagnosis must be made on clinical grounds alone. We have neither definite etiologic knowledge nor laboratory diagnostic methods The skin manifestations present congestion, thickening and pigmentation and atrophic thinning The eruption may begin as macules which fuse, forming patches of livid red erythema The tissues are generally swollen In a short time the redness fades and the surface becomes covered with scales In some cases vesicles bullae and ecchymotic lesions complicate the process The surface may become raw The skin may resume a normal appearance, but after several recurrences it atrophies A symmetric distribution of the lesions is characteristic Itching and burning often precede the eruption At the beginning it may resemble a sunburn Skin diseases resembling pellagra are acrodynia, erythema solare, erythema caloricum, erythema ab igne, erythema pernio, erythema multiforme, eczema, trade dermatitis, dermatitis venenata lupus syphilis and erysipelas Acrodynia somewhat resembles pellagra, but runs a shorter course, rarely ever recurs, and is rare Sunburn resembles the early rash of pellagra, but the area is usually less acutely inflamed There is less redness, and it gradually fades instead of becoming darker as in pellagra, and is followed by less exfoliation Erythema multiforme is prone to recur, is usually seen in spring and autumn, and is accompanied by nervous and gastro-intestinal symptoms It differs from pellagra in that the eruption is found on the flexor oftener than on the extensor surfaces, and seldom on the face, rarely involves the entire surface does not exfoliate and is not followed by pigmentation Its duration is short

Erythema and eczema may be mistaken for pellagra eruptions It generally begins as macules or erythematous spots with swelling accompanied by excessive burning and itching Desquamation begins in a few days and often continues for several weeks and may become chronic Exposure to heat, cold wind and other irritants often causes an outbreak. It differs from pellagra in that it occurs at all seasons is not symmetric is usually seen on the flexor surfaces as well as on the extensor the edema is more marked and it is accompanied with more itching and burning The differentiation from dermatitis venenata can usually be made by the history, duration and location of the eruption

Lupus erythematosus disseminatus can usually be distinguished by the location, shape, time of occurrence color, course duration and other symptoms of pellagra Syphilitic eruptions can usually be differentiated by the history of a primary lesion, the secondary rash on the body, character of eruption positive Wassermann and other symptoms of syphilis

Pellagra

Dr H W Dudgeon, Director, Khanka Lunatic Asylum, Cairo Egypt I can only reiterate my belief in the maize theory of pellagra which is extremely prevalent in Egypt. I have examined physically many thousands of residents of Egypt (mostly Egyptians) from all districts and from all classes of society during the last fourteen years, and it has been impressed most strongly on me how entirely this disease is confined to the villagers of the poor class, it is almost unknown among those who live in the towns and it is also most uncommon in the districts (Upper Egypt) where millet is grown The Egyptian villager's diet has maize as the main ingredient and wherever maize is the staple form of diet there you find pellagra In fact, it is so rife among the villagers that I doubt if it can have been endemic to this country for a great number of years, and with this idea and the similarity of many of the symptoms to some accounts I was able to obtain of chronic atropin poisoning I sent a certain number of specimens of maize to England for analysis with the attempt to see if the alkaloid atropin or its allied group of alkaloids were present No atropin was found but the leaves of certain specimens did contain an alkaloid and one of them did not The alkaloid was too small in amount for identification but it was sufficient to prove that it was not one of the more commonly known alkaloids and the leaves of the specimen happened to be that of the oldest species of maize cultivated in Egypt. My opinion is that pellagra is a multiple neuritis and may be due to an alkaloid administered in minute doses, possibly by the seeds absorbing the poison from the leaves, and that it is accidental and due to maize faultily stored it is evidently not normally found in maize seeds nor do I think all kinds of maize leaves contain it.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below

American Journal of Diseases of Children, Chicago

December X, No 6 pp 397 488

1 *Duodenal Ulcer in Infancy an Infectious Disease L Gerdine and H F Helmholz, Chicago
2 Comfortable Arrangement for Separate Collection of Urine and Feces of Male Infants A. M. Courtney and H L Fales, New York.
3 Oxalic Acid Excretion in Urine of Children J P Sedgwick, Minneapolis
4 Phthalein Test in Orthostatic Albuminuria T C Hempelmann, St Louis.
5 Influence of Clothing on Surface Temperature of Infants W B McClure and L W Sauer, Chicago
6 *Ammoniacal Diaper in Infants and Young Children J Zahorsky, St Louis.
7 Acute Myelitis Following Varicella, Report of Case. D C W Smith, Baltimore

1 **Duodenal Ulcer**—In ten out of fourteen ulcers examined by the authors, diplococci were found in the ulcer base, in such numbers and in such a position that they presumably are of etiologic significance Furthermore, in one of the cases a *Streptococcus viridans* was isolated from the duodenal ulcer, which on injection into rabbits and dogs localized in the pyloric end of the stomach and duodenum and there produced hemorrhages and ulcerations This case was the only one in which the authors were able to obtain the organisms in pure culture, and the only one in which the necropsy was performed shortly after death In two other cases a few streptococci were seen in the bouillon cultures, but the cultures were so overgrown with colon bacilli that it was impossible to isolate the streptococci In one case only the colon bacillus was grown

6 **Ammoniacal Diaper**—The ammoniacal diaper is frequently encountered by the practitioner Usually, the odor of ammonia is faint, especially in young infants Only occasionally does the concentration become sufficiently intense to produce the characteristic irritation of the skin The lesions consist of inflamed areas on the inner side of the thighs, the genitals, the buttocks and lower abdomen The skin lesions nearly always appear in the morning when the infant has lain for a long period during the night Infants who do not wet the diaper are not subject to this trouble In fact, enuresis and ammoniuria go together The ammoniacal diaper is a frequent precursor of pyelocystitis in female infants The onset is usually abrupt and the course is irregular and indefinite The irritating urine may be present for one day only, then it may last for weeks Zahorsky has collected notes of seventy-eight cases, in all of which the patients showed some skin lesions, and the ammonia was sufficiently intense to warrant more than a passing notice Of these seventy-eight cases, fifty-four, or about three fourths, occurred in children over 10 months of age The severest lesions occurred in boys The disorder seems to be almost limited to artificially fed infants Zahorsky has searched long for the cause of this disorder and he is now convinced that the ammonia is derived from the ammonium compounds in the urine, and is liberated by an alkali present in the diaper—soap, lye, lime or stool

20 *Pregnancy and Diabetes Mellitus E P Joslin, Boston
21 Surgical Specialties in Hospitals P Thorndike, Boston
22 *Etiology and Treatment of Heart Disease P D White, Boston

17 **Treatment of Chronic Empyema**—Lund says that in localized chronic empyema, decortication has usually given most brilliant results and been successful the first time Decortication is not a cure-all or specific It must be thoroughly and intelligently used, and must be preceded and followed by all the tricks and dodges which experience can suggest to secure lung expansion, except those methods which imply suction apparatus and provide an inadequate drainage opening It may have to be supplemented in certain obstinate cases by rib resection On the whole, however, and properly used, it must be regarded as an invaluable method in cases in which the later simple methods fail to cure, and the ultra radical methods are sure to kill patients

18 **Surgery of Lung Abscess and Bronchiectasis**—Although the operation for acute empyema may be a simple one, yet, Whittemore says, the results have been far from satisfactory After an acute case becomes chronic, the outlook for the patient becoming a useful member of the community is questionable Surgery has little, if anything, to offer cases of bronchiectasis at present The surgery of lung abscess is most encouraging, and a greater number of cases are constantly being successfully operated on

20 **Pregnancy and Diabetes Mellitus**—Out of the seven cases of moderate or severe diabetes associated with pregnancy cited by Joslin, four patients are dead, one by suicide, one with uremic manifestations ascribed to neglect, a third died in coma, pregnancy having developed after diabetes had existed for a year, but treatment was neglected, the patient later being under the care of a clairvoyant, and the fourth in which the patient successfully went through her first pregnancy in 1897 with a healthy child, but again was confined and the child lost in 1905, the patient dying two months later of pulmonary tuberculosis Of the three remaining patients, one is in exceptionally good health, free from sugar and has a normal child six months after delivery, another is in a tolerable condition, having been pregnant three times but with only one child now living, and the remaining patient is alive, although severely ill with diabetes six years after confinement All of the seven patients with moderate quantities of sugar in the urine are well

Joslin says that the secret of success in the treatment of pregnant women with sugar in the urine is 1 To have the patients under constant supervision throughout the course of the pregnancy and for some months after confinement 2 Treatment should follow exactly the same methods which are employed in the treatment of the usual case of diabetes 3 Even when sugar appears to a slight extent in pregnant women, it should be carefully watched and controlled by diet 4 The advantages of a cesarean section should be borne in mind 5 Whereas ether anesthesia may work well, it is probably not so safe as gas and oxygen If ether should be used, as brief an anesthesia and as little ether as possible should be employed 6 Finally, many statements occurring in the literature of pregnancy and diabetes must be revised Pregnancy in diabetes does not demand immediate abortion, even if acidosis is present If pregnant diabetic cases are suitably managed, they will likely abort less frequently It cannot yet be accepted as proved that pregnancy aggravates a diabetes It is quite possible that the reason for a patient with diabetes becoming worse during pregnancy is simply due to the ingestion of an unusual quantity of food Nursing is not contraindicated following confinement, for the diversion which it affords the patient may offset the extra demands thrown on the metabolism

22 **Treatment of Heart Disease**—White summarizes his study of 200 cases as follows The male sex is more subject to auricular fibrillation, auricular flutter, heart block and alternation of the pulse than the female sex The older the patient with heart disease the more subject is he to serious abnormalities of the heart beat Auricular fibrillation and alternation of the pulse occur at the same ages, most frequently in the fifth and sixth decades Rheumatic hearts usually show normal mechanism or auricular fibrillation, much less commonly pulsus alternans A considerable percentage (36 per cent) of syphilitic hearts showed alternating pulse, few were fibrillating A patient with cardiac insufficiency in the course of cardiorenal disease is apt to show pulsus alternans, either constant or more frequently only after ventricular premature beats Cardiosclerosis often results in the production of fibrillation and alternation Hyperthyroidism of long standing is sometimes attended by auricular fibrillation Alcohol, tobacco, tea and coffee appear to play no direct part in the production of serious disorders of the heart beat Two thirds of the patients with auricular fibrillation, one half of those with alternation of the pulse, and one-third of those with normal mechanism in the series analyzed by White showed physical signs of cardiac insufficiency Digitalis was used in 88 per cent of these decompensated cases, almost always in the form of pills of standardized leaves Intravenous medication was used in urgent cases only Morphin was given beneficially in nearly one half of the patients with physical signs of insufficiency, often one dose sufficing to give the patient the first comfortable night in weeks Venesection was found useful in a few urgent cases The change in diet to five small meals daily was often much appreciated by the patient

31 **Relation of Spleen to Blood Destruction**—The experiments reported on by Austin and Pepper indicate that when hemoglobin is set free in the portal circulation a larger amount is held by the liver and converted rapidly into bile pigment than is the case when it is set free in the general circulation, and that, under the former condition, overloading of the liver with bile pigment more readily occurs and jaundice is more apt to develop The authors conclude that this mechanical influence must, therefore, be a factor in the lessened tendency after splenectomy to the jaundice which follows blood destruction due to hemolytic agents for whether the spleen be an active factor in destroying the erythrocytes, or whether it plays merely a passive part as a place for the deposition of the disintegrating cells, there can be no question that in this organ when it is present, a large number of cells undergo their final disintegration after the action of hemolytic poisons, and that the hemoglobin there liberated passes by the portal system directly to the liver When the spleen is removed, this disintegration occurs in other organs, notably, in the lymph nodes and bone marrow, and the hemoglobin from these organs passes not into the portal but into the general circulation, from which it reaches the liver more gradually and in a more dilute form

32 **Influence of Diet on Anemia Following Splenectomy**—The author's experiments showed that the anemia which develops after splenectomy is most marked in animals on a mixed table scrap diet of meat, bread, cereals and vegetables, which is essentially a cooked diet Control studies in which a unilateral nephrectomy precedes splenectomy demonstrate that the anemia is not due to operation, hemorrhage, or accidents of convalescence, but develops only in the absence of the spleen The results of studies of the influence of food containing a large amount of iron in presumably easily utilizable form as in raw beef spleen, do not support the view that the anemia is due to lack of iron in the food Observation on the influence of a diet of raw meat as contrasted with cooked meat, shows a more severe anemia in animals on the cooked diet and suggests the possibility that heat alters some substance which, in the absence of the spleen the body cannot utilize A final conclusion in regard to this point must, however await the results of more detailed studies now in progress

37 **Removal of External Function of Pancreas**—Quite by accident Sweet and Ellis noted in two cases that the complete removal of the function of the pancreas concerned in digestion is followed by marked changes in the spleen and in the thyroid apparatus Second the spleen shows an extreme simple atrophy Third, the thyroid apparatus exhibits a constant change shown by the macroscopic transparency of the gland, by the microscopic increase in the amount of colloid by the chemical increase of the iodin content of the gland and by the functional test of the delayed appearance of tetany after the complete removal of the thyroid apparatus

38 **Influence of Desiccated Thyroid on Tadpoles**—The activity and potency of the physiologically active substance of the thyroid, Lenhart states, is measurable in terms of its percentage iodin content He points out that the reaction of tadpoles to thyroid feeding is so sensitive that the procedure might well serve as a biologic test for the activity of thyroid tissue, superior even to chemical methods

39 **Experimental Pneumonia**—The studies described by Sisson and Walker are based on findings in thirty-nine cats The culture used was recovered from the lung exudate of a patient who died thirty-one and one-half hours after the onset of the first symptoms The organism had the characteristics of *Bacillus mucosus capsulatus* Judging both from the clinical course and from the pathologic findings, this form of pulmonary infection differs from the usual

pneumococcus types of pneumonia and closely resembles the so-called Friedländer's bacillus or *Bacillus pneumoniae* in man In all instances in which a lobar pneumonia was found after the injection of the bacillus, a similar organism was recovered from the lung, and in no case was this associated with other organisms In 87 per cent of the animals showing a lobar pneumonia positive blood cultures were obtained The pathologic findings, judging from the early stages of the disease, are subject to considerable variation In some instances the process may suggest a pseudolobar or confluent lobular distribution In the majority of cases, however, the process gave a more homogeneous appearance, suggesting a diffuse and uniform distribution Foci of hemorrhage were not uncommon in both In all instances the consolidated lung presents a greater infiltration of tissue than is usually seen in other types of experimental pneumonia The histologic findings are also subject to considerable variation In most instances the infundibular and alveolar spaces are completely filled with an exudate made up chiefly of polymorphonuclear cells Associated with these are the capsulated bacilli, large vacuolated mononuclear phagocytic cells, and red blood cells and occasionally small amounts of fibrin

41 **Diet and Tumor Growth**—Woglom found that lactose does not increase the receptivity of mice and rats for the transplantable carcinomas of their species

42 **Antityphoid Vaccination**—Evidence is presented by Nichols on the following subjects (1) the infectious power of a living, sensitized vaccine, (2) the absence of immunity in vaccinated rabbits to direct gallbladder infections, (3) the relative pathogenicity, virulence, and toxicity of the strain used in the army vaccine, (4) local vaccine reactions after typhoid and after immunization, and (5) skin reactions as an index of immunity

44 **Rate of Growth of Tumors in Mice**—According to Murphy and Morton Roentgen ray administered directly to the cancer outside of the body is insufficient to prevent the growth of a graft returned to the original host On the other hand, the same small dose of Roentgen ray given to the animal with the cancer removed was sufficient to render 50 per cent of the mice so treated immune to returned untreated grafts of their own tumors and greatly retard the growth in the other 50 per cent

48 **Nephrectomy During Pregnancy**—From the literature as well as from personal observation, Schmidt has come to the conclusion that a woman with one healthy kidney—and that implies that no infection remains whether it be tuberculosis or a pyogenic infection—does not carry much greater risk, nor does the fetus, than the more fortunate woman who has two kidneys, and that consent to marriage and pregnancy cannot be withheld There are questions such as how soon after nephrectomy may one, without danger, become pregnant Schmidt is of the belief that if a period of several years of complete absence of kidney disease elapses it is safe There is a greater need for exact observation of these cases, so that in case of the recurrence of any (nephritic) symptoms, induced abortion or labor can be carried out in order to prevent chronic kidney changes which might result in making an invalid of a woman having only one kidney

52 **Rôle of Oxyuris in Etiology of Appendicitis**—Suzuki examined 500 post mortem cases, among which were 44 oxyuris cases The oxyures were found twenty-nine times (66 per cent) in the cecum and appendix, six times (14 per cent) in the cecum alone, and nine times (20 per cent) in the appendix alone Suzuki was able to ascertain that a true inflammation is provoked by the parasites when the latter have penetrated the wall of the appendix in large numbers, and that the traumatically destroyed fissure in the tissue is for a protracted period of time in connection with the lumen, thus offering the infecting agent a portal of entry This type of the disease offers distinct histologic data, for which reason Suzuki has designated it "appendicitis oxyurica" But this type of the disease is only rarely met, and among 103 surgically extirpated appendices Suzuki met but one case A noninflammatory, but pain-producing morbid condition of the appendix is sometimes caused by the oxyuris in which cases traumatic destruction of the tissue accompanied by hemorrhage can always be demonstrated

54 **Fracture of Femoral Shaft, End-Results**—Martin found that 90 per cent of all cases of simple fracture of the shaft of the femur in children are followed by complete recovery The average period of treatment of children in bed and with crutches, splints and bandages is two to three months Between the ages of 15 and 25 years there is about 50 per cent of complete recoveries, while after 25 years the permanent disability is proportionate to the age of the patient Men above 40 years rarely regain strength and activity In adults in the absence of shortening there may be a lasting weakness of the leg and thigh Permanent disability is as a rule associated with shortening, and is to an extent proportionate to the degree of shortening The average time in bed and with crutches, splints, and bandages in adults is eight months In adults at time of discharge (eight to ten weeks) there is stiffness of the knee in 100 per cent of cases Among adult laboring men, 90 per cent never become able to perform their regular occupations Among adult males not of the laboring class, the great majority are able to perform their regular occupations The unsatisfactory results following the weight extension treatment of simple fracture of the femoral shaft in adults suggest that this method is either inadequate in itself or unskilfully applied Efforts for obtaining better results in adults should be directed to (a) the employment of more weight in procuring extension, in the effort to entirely overcome the deformity, (b) early resort to open operation if extension seems inefficient, (c) the systematic use of massage and passive motion continued for months, (d) a longer use of crutches than is now customary, (e) education of the patient

61 **New Operation for Umbilical Hernia.**—The surgical principles involved in Dubose's operation provide for the attachment of the umbilical ligaments at a point in the suture lines so that the pull exerted by them does not favor gaping The neck of the sac is isolated, opened, and its contents freed and returned into the abdomen, it is then amputated, and the peritoneal edges everted and approximated by a running mattress or purse-string suture A transverse incision is made at the upper, and a parallel incision at the lower margin of the umbilical ring, thus

mobilizing two lateral fascial flaps to be united by interrupted sutures Running in the long axis of each flap is the third tendinous intersection of the rectus abdominis muscle The edges of the upper and lower lines of incision are brought together by interrupted sutures, thus forming a double aponeurotic wall, with lines of approximation at right angles Two figure-of-eight silkworm-gut sutures are introduced, going deeply enough to catch the underlying fascial flap, and brought out through the skin an inch from the margin of the incision When these are tied they relieve the strain in all directions on the aponeurotic lines of union and close the dead space in the subcutaneous fat On the posterior surface of the lateral aponeurotic flaps is the attachment of the umbilical ligaments When the inner ends of these flaps are sutured together the hernial opening in the umbilical ring is closed and the attachment of the round ligament of the liver above and of the urachus and the obliterated umbilical arteries below are restored anatomically All traction exerted by these ligaments pulls on the upper and lower ends of the line of approximation of the two lateral flaps, thus having a tendency to close and not to pull apart the sutured edges of these two flaps

63 **Operation of Hernia Between Abdominal Recti**—The operation proposed by Fairfield depends essentially on the conversion of the two fascial spaces containing the recti into one space, obliterating thereby the natural separation of the two muscles, and interposing both muscles over the hernial point.

1 **Ileus Duplex**—Ileus duplex, according to Handley, who has supplied the name, is a condition in which, as the result of a pelvic peritonitis there is obstruction of the intestine at two points (a) In the ileum, at a point about 3 feet above the ileocecal valve, (b) in the sigmoid colon, at the junction of its iliac and pelvic portions These are the points at which the ileum and colon, respectively, cross the brim of the true pelvis to enter the pelvic cavity The segments of paralyzed intestine are two in number First, the portion of ileum contained in the pelvis, that is to say, about the lower 3 feet excluding the last 2 inches, and second, the portion of the large bowel contained in the true pelvis, namely, the lowest portion of the pelvic colon and the upper portion of the rectum The condition, though curable by appropriate treatment, in the early stage often passes unrecognized under the pseudonym of general peritonitis

2. **Visceroptosis**—Sixty-seven cases have been analyzed by Walton. They have been divided into the following groups according to the disease they simulate (1) Cases resembling appendicitis, (2) cases resembling gastric ulcer, (3) cases resembling gallstones, (4) cases resembling gastric carcinoma Twenty-nine cases were diagnosed as appendicitis Of the twenty-nine cases, thirteen have resembled acute and sixteen chronic appendicitis, but this group does not include cases of true chronic or acute appendicitis in which visceroptosis was also present. There were twenty-seven cases resembling gastric ulcer, but five of them must be considered apart from the others These five patients showed well-marked evidence of visceroptosis, but in addition had either a gastric or duodenal ulcer The remaining twenty-two showed visceroptosis alone They were of the type frequently operated on in the belief that a gastric ulcer was present At operation, there was no trace of an ulcer in the stomach or duodenum The operative procedures consisted in dividing any excessive bands or adhesions, and if the appendix was bound down by the Jackson's membrane, it was removed In one patient only, in whom the stomach appeared to be hypertrophied, and in whom there was an excessive pyloric spasm, the pylorus was occluded and a posterior gastro-enterostomy performed In two patients the right kidney was exceedingly movable, and nephrorrhaphy was carried out

The results of operative treatment could not be considered satisfactory as a whole Nearly all the patients showed marked relief for two to six months, but after that time the symptoms gradually returned There were six patients whose symptoms resembled those given by gallstones At operation there were found the same general visceroptosis, the presence of bands and membranes and the evidence of local spasm in the stomach wall In two of the patients the kidney was found to be so mobile that it was considered wise to fix it through another incision in the loin Apart from this, the operative procedures consisted of division of the adventitious bands and adhesions and, if necessary, removal of the appendix Later an abdominal belt was ordered There were five cases resembling carcinoma of the stomach All five cases presented a short history At operation, there was no evidence of carcinoma or other organic gastric lesion Each case, however, showed certain characteristics of the condition of visceroptosis The results of operation were again not wholly satisfactory

3 **Paget's Disease**—Jefferson suggests that Paget's disease is in all probability not an inflammation, but an upset of the internal secretions (especially thyroparathyroid) which control the calcium exchange of the body The early stages of the disease are characterized by a general decalcification, bringing the affection into line with osteomyelitis fibrosa and to a limited extent with osteomalacia At the same time an irregular bony proliferation occurs, sufficient in amount to overshadow in the urinary and intestinal excretion the absorbed bone salts The disease may progress along different lines, presenting itself as an osteomyelitis fibrosa, or having excessive lime deposits, the average case being the mean between the two Although a general disease, certain bones are more severely affected than others The disease may be impossible to diagnose while a single bone is affected, though the Roentgen rays will often reveal disease in the early stages in other bones in which it had not been thought to exist Later, bone salts are deposited in large amounts, this stage being associated with calcium magnesium and phosphorus retention, as has been proved by experiment. During the stage of softening which may be prolonged and gradual, deformities are produced in all the bones, including the skull The several varieties of bone change which have been described by various observers of this disease, may be explained by the morphologic differences which the bones present at different stages of the malady, and the different types—the fibrous or the osseous tissue predominating—which it may assume Benefit may be looked for from the oral administration of extracts of internal secretory glands, though once deformities have occurred they will persist even if the disease is arrested

6 **Treatment of Wounds by Magnesium Sulphate Solution.**—A saturated solution of magnesium sulphate has given

Morison the best results, both clinically and experimentally Forty ounces of magnesium sulphate dissolved in 10 ounces of glycerin and 30 ounces of boiling water, and sterilized in an autoclave, makes the solution ready for use The application is painless, is easily carried out, and the dressings, even in the most septic cases, need only to be changed twice a day In recent injuries the wound is freely opened up, the bullet, portion of shell, clothing or other foreign body is removed, and the whole wounded surface is swabbed with pure phenol In the case of fractures, the ends of the bone are treated in the same way, and loose but attached fragments are not removed The wound is gently packed for twenty-four hours with gauze wrung out of phenol lotion (1 in 20), and antiseptic wool applied as an outer dressing At the end of this time the wound is dressed, the gauze plug is removed, the wound is syringed out with magnesium sulphate solution, and loosely packed with sterile gauze wrung not too hard out of the same solution, and the whole area of the wound is then covered with a double layer of gauze or lint saturated with solution, over which a piece of jaconet, then cottonwool, is placed, the whole being fixed loosely by a bandage In the case of wounds of later date, in which sepsis and suppuration are fully established, the treatment by phenol is omitted and magnesium sulphate solution is commenced at once

Dressings, even in the worst cases, are only changed every twelve hours, thus saving the patient much discomfort and trouble Morison states that the effect on the wound is striking In two or three days pus has almost disappeared, sloughs begin to separate, and the whole surface of the wound presents a bright-red color The granulations never become flabby or edematous, but instead a firm, vascular healing wound is seen The growth of epithelium from the edges of the wound proceeds vigorously, and the treatment may be continued with advantage until the entire wound is healed Constitutional symptoms seldom occur, probably owing to the fact that absorption is prevented by the density of the granulations, there is, therefore, no general disturbance of health, there is an absence of lymphatic and glandular infection, and secondary abscesses are almost unknown The effect in the majority of compound fractures is quickly manifest Pus rapidly disappears, and the amount of necrosis in comminuted cases appears, as would be expected when infection is diminished, to be materially less

18 Bacterial Antagonism, with Particular Reference to Meningococcus L. Colebrook
19 Blackwater Fever R. W Burkitt.

17 **Trench Fever**—In twenty-three of the thirty cases studied by Hunt and Rankin, the onset was sudden, in seven more gradual In the former case the disease began with head-headache, dizziness and shivering, in the latter with headache and general malaise The chief symptoms were headache and pain in the back and legs Headache occurred in every case It was rarely severe, and in two cases only was it intense, it was usually frontal Pain in the lumbar region was present in twenty-seven cases, pain in the legs in twenty-six, in no case was it severe Pain and stiffness in the neck was rare. Abdominal pain occurred in four patients radiating round from the back, and was probably of muscular origin Dizziness was complained of in the majority of cases, and was an early symptom, but sometimes it persisted for several days Two patients fainted at the beginning of the illness Vomiting was rare (four patients only), and was never persistent, in every case it was associated with and probably due to obstinate constipation Constipation was present in seven patients, diarrhea only occurred once, and then lasted one day Dryness of the throat was complained of by two patients, but in neither case was there any redness of the fauces

The most striking feature in the condition of the patients was the absence of any objective signs There was little constitutional disturbance, and only three patients looked really ill The temperature was at first raised, then fell to normal, and this fall was followed by one or more relapses With each relapse there was a recurrence or an aggravation of the symptoms The pulse rate was not raised out of proportion to the fever The tongue was sometimes clean, but more often was slightly furred, in three patients it was thickly coated There was generally some tenderness over the back and legs, but it was always slight, in four patients there was a little tenderness of the abdominal muscles The heart and lungs showed no abnormal signs, and bronchitis was always absent The spleen and liver were not enlarged The urine was free from albumin In one patient herpes labialis was present. The investigations undertaken with the object of attempting to establish something definite in regard to the etiology of this fever have been disappointing It is certain that the disease is not contagious in any high degree, for, although no precautions for isolation were taken, no patients in the same ward developed the disease One orderly in the ward, however, had a typical attack with one relapse

30 *Further Research on Vaccination against Paratyphoid J Lignières (Buenos Aires)

23 **Rigidity as Sign of Impending Gangrene**—Prat reports four cases of severe wounds in which the limb became rigid in a few hours and gangrene soon followed His experience indicates that this rigidity is practically cadaveric rigidity, from chemical changes in the muscle tissue, with incipient but extensive gangrene Prompt amputation saved three of the men, while the others died under conservative operation

24 **Inefficacy of Oral Vaccination Against Typhoid**—The research reported with tests for agglutinins, precipitins, deviation of complement and opsonic index all testified anew to the utter inefficiency of antityphoid vaccines taken by the mouth

26 **Epidemic Meningitis**—Capitan reports that thirty-four of the forty-five men with meningococcus meningitis recovered under serotherapy, and three of the five with mixed infection Convalescence was always very long and slow weakness and anemia persisting for weeks, even when there had been no complications Treatment was by lumbar puncture, withdrawing as much fluid as possible, usually 20 or

30 c c or more, and injecting from 30 to 60 c c of the therapeutic serum, repeating this daily, for several days, sometimes skipping a day, and sometimes resuming treatment after an interval In this latter case 1 or 2 c c of the serum were injected into a muscle four hours before the intraspinal injection, and no symptoms of anaphylaxis developed in any instance As a further adjuvant, a mixture was given of 4 parts calcium chlorid, 2 parts extract of cinchona and 0 1 part spartein sulphate This supplied a heart stimulant, while combating any tendency to serum sickness

30 **Vaccination Against Paratyphoid in Man and Animals** —Lignieres calls attention to the progressive attenuation of virulence in strains of paratyphoid bacilli cultivated in the laboratory They finally become quite harmless, losing their pathogenic properties, and he warns that vaccines made from such laboratory strains seldom have any prophylactic or curative power The best vaccines are those made with microbes derived recently from spontaneous and grave cases of paratyphoid infection He calls it 'salmonellosis,' referring to the research he published in 1900 in which he apparently demonstrated that certain forms of hemorrhagic septicemia in domestic animals were the work of two species of paratyphoid bacilli to which he gave the name salmonella and pasteurella The former is of the hog cholera, the latter of the fowl cholera type His experience with salmonella derived from recent grave spontaneous cases showed that vaccines could be made sufficiently powerful to immunize sheep and pigs by the mouth against fatal infection He has not been so successful with oral immunization of cattle to date

34 **Voluntary Mutilations to Escape Military Service** —In some recent sensational cases in France the supreme court decided that the medical experts had been mistaken in assuming that certain mutilations had been done by the individuals in question for malingering purposes In two cases in particular the supreme court reversed without appeal the judgment imposing the death penalty for voluntary mutilation, rebuking the experts on whose testimony the men had been condemned Chavigny here discusses the ethical questions that arise when one suspects malingering of this type Several times the majority of the men reaching the ambulance after an engagement were wounded in the hand and voluntary mutilation seemed the only explanation until it was realized that the men whose legs were not injured reached the hospital quicker naturally than those that had to be carried In some other cases of men accused of voluntary mutilations roentgenoscopy finally revealed a scrap of shell in the tissues In any event the physician should testify only as to the conditions of the wound the direction distance etc but he can never know positively whether the wound was inflicted by the man himself or an awkward comrade or some coconspirator or some enemy at close range This can be determined only by the testimony of witnesses It is useless unjustified and imprudent for the physician to draw conclusions in such cases The authorities recognize this a decree last May emphasizing that the testimony of the medical expert alone is not sufficient for a verdict of voluntary mutilation

Chavigny knows of some instances in which voluntary mutilation was realized by the man s holding his hand up out of the trench, so that the enemy might shoot it, in other cases the man claimed to have shot his left hand or right foot while cleaning his gun In still others the men wrapped the part in a wet cloth before putting the bullet through it, thus preventing powder marks

41 *Typhoid Fever and Antityphoid Vaccination L. Rimbaud
42 *Hemotherapy of Typhus. Escluse
43 Thiosinamin in After Treatment of Wounded Nerves. P Cazamian

38 **Albuminuria as Sign of Meningeal Hemorrhage** —Guillain replies to Macris' communication, summarized in these columns Sept 11, 1915 p 986 He explains that the albuminuria to which he refers is of sudden onset, reaching 2, 10 or 20 gm per liter in one or two days after the meningeal hemorrhage and then rapidly subsiding until in a few days the urine may be nearly or quite free from albumin He has noticed it only in a few cases and found records of only a few cases in the literature But when this massive albuminuria is encountered in a dubious case, it has much semeiologic importance

39 **Leverage in Reduction of Dislocations** —Cochez uses a crutch with long crossbar at right angles near the foot for applying gradual automatic traction, the crutch rest serving as the lever This contrivance is proving extremely useful in reduction of recent and old dislocations of the shoulder, elbow hip joint and knee, as he describes in detail with five illustrations It does away with the necessity for counter traction while the reduction proceeds with mathematic regularity under constant control with the dynamometer Traction equivalent to 60 or 80 kg (176 pounds) can thus be exerted without jerk or shock

41 **Vaccination Against Typhoid** —Rimbaud deplores that the present technic for vaccination against typhoid does not protect against paratyphoid This has continued its ravages, while typhoid has been nearly stamped out in the French army in the region where he is stationed There were 222 cases of typhoid in the nonvaccinated, and typhoid bacilli were cultivated from the blood in 50.9 per cent., but paratyphoid bacilli were found only in 10.3 per cent while the latter bacilli were found in 35 per cent of the 434 vaccinated who developed a typhoidal condition True typhoid bacilli were found in 19 per cent of the 21 vaccinated but once, in 11 6 per cent of the 146 vaccinated three times, and only in 6 8 per cent of the 145 fourfold vaccinated

42 **Hemotherapy in Typhus** —Escluse made intravenous injections of blood taken from convalescents eight or ten days after defervescence and reports that the severe typhus showed a prompt change for the better in the three patients given this treatment The technic was similar to that for ordinary transfusion of blood only that a little sodium citrate was mixed with the blood The cases selected for this treatment were extremely grave, the prognosis unfavorable The experiences related demonstrated that after the organic reaction is exhausted by the severity of the typhus intoxication the hemotherapy is unavailing There is not much chance of success after the tenth day The maximum amounts injected were 30 c c of blood fractioned in three doses during the twenty-four hours, a total of six injections in the course of three days in one case and three injections in four days in the other

46 *Symphysiotomy or Cesarean Section (Symphysiotomie oder Kaiserschnitt) P Hüssy
47 Medicologal Aspects of Perforation of the Living Child (Perforation und Strafgesetzreform) H Lieske

44 **Causes that Influence the Position of the Fetus**—This long article is the second which Schatz has published on this subject It reports the results of extensive clinical research which explain the mechanism of the changes of position of the fetus, the influence of the position of the uterus, and other factors The findings on repeated examination of pregnant women near term, reclining or erect, are given in 140 tables The influence of the sex and size of the fetus, of the time of day, of the contractions of the uterus, influence of preceding deliveries, and the way in which the fetus changes its position and presentation are all discussed in detail The efforts of the fetus to stretch its limbs seem to be the main cause of its changes of position He found that the fetuses displayed as marked characters as in extra-uterine life Some were nervously alert and responded promptly and vigorously to altered conditions, while others were torpid and sluggish and seemed to be governed only by the law of gravity, thus getting into the breech presentation attitude and keeping it

45 **Tests of Kidney Functioning During Pregnancy and the Puerperium.**—Werner gives the conclusions from repeated testing of the work of the kidneys in 28 women with puerperal eclampsia, including 23 primiparas The eclampsia was not of the fulminating type and none of the women died Ten other women examined had pregnancy kidney, quite severe in 3, and terminating in eclampsia In 5 other cases nephritis developed in the course of a pregnancy Nine other women presented pregnancy glucosuria, but tests of kidney functioning showed nothing abnormal Seven other women had pyelitis, but the kidney functioning seemed normal as the tubular system in the sound mate was able to do all the needed work When both kidneys were affected, the tests showed manifest functional impairment The tests were applied also to 15 women who had been delivered under a general anesthetic (Billroth mixture) on account of myomectomy, cesarean section or laparotomy for other cause Eight other women had valvular defects In addition to this clinical material, the tests were applied to 20 healthy women pregnant for the first time and approaching term, 15 primiparas, 8 multigravidas, and 8 multiparas The tests were the usual lactose, iodin and phenolsulphonephthalein technics Necropsy in 4 cases confirmed the findings of the tests

The conclusions drawn from this extensive material are that in healthy pregnant and parturient women the functional capacity of the kidneys is good but not quite up to standard, although the tubuli seem to functionate periodically a little more than under normal conditions After operative deliveries under general anesthesia, both the glomeruli and the tubules show slight but transient impairment of function Compensated valvular defects showed a good response to the iodin and phenolsulphonephthalein tests, but the lactose test revealed some damage of the kidneys With pregnancy glucosuria, the glomerulus functioning was evidently impaired, while the tubuli behaved normally Four of the 6 pregnant women with pronounced goiter responded to the lactose test with glucosuria, indicating weakness of the glomerulus system while the tubule function seemed intact Both systems showed severe impairment in the cases of nephritis, but the tubular functioning soon recuperated after delivery while the glomerular functioning showed scarcely any influence from this

The lactose and iodid tests are thus important aids in distinguishing between actual nephritis and mere nephropathy, and they aid in the prognosis with the latter, as the form with vascular disturbances manifests a marked tendency to become chronic after the termination of the pregnancy The kidneys in eclampsia responded to the tests the same as the "pregnancy kidney," namely, the response to the lactose test was as in normal conditions, but the response to the iodid test ranged between wide extremes, the elimination of the iodid being complete in thirty hours in two cases, in forty-five hours in ten, and not until after the sixtieth hour in two

46 **Symphysiotomy or Cesarean Section**—Hüssy has delivered eight women by Frank's subcutaneous method of symphysiotomy and is convinced that it must be regarded as progress It takes the place of perforation of the living child with a true conjugate down to 7 cm and spontaneous delivery not entirely out of the question It allows waiting as long as the fetal heart sounds are normal It does not compete with extraperitoneal cesarean section, as the latter is indicated when there is manifest infection or spontaneous delivery is out of the question Subcutaneous symphysiotomy is not especially dangerous, although thrombosis seems particularly imminent with it and the damage to the soft parts may have serious consequences

Correspondenz-Blatt für Schweizer Aerzte, Basel

November 6, XLV, No 45, pp 1409 1440

48 *Treatment of Sterility in Women (Behandlung der weiblichen Unfruchtbarkeit.) E von Fellenberg
49 Experiences in a German Base Hospital G Hotz.

48 **Treatment of Sterility in Women**—Fellenberg is convinced that the internal secretions have an important share in preventing conception in some cases Inhibition of the functioning of the sound ovary from a cystic ovary was apparently responsible for the sterility in one of his cases, as the long childless couple had a child born within one year after the cystic ovary had been removed Such inhibition used to be ascribed to nervous influences, but now we explain them by internal secretions, and this permits the hope of effectual treatment of sterility from this cause The genital organs in particular are under the control of the ductless glands, and the secondary sexual characters include not only those of the external genitals and the breasts, but also the changes in the birth tract An infantile condition of the genital organs is generally associated with a chlorotic anemic habitus It is possible that only single segments of the genital organs may fail to develop normally It is also possible that the changes occurring at puberty may exhaust the organism for a time or permanently, and that the ovaries then are unable to functionate normally By giving ovarian extract, the missing stimulus may be supplied and conditions gradually right themselves, permitting conception in time Bab in 1909 strongly commended this treatment, supplemented with lecithin to enable the mother to supply the fetus' need of lecithin He applied measures also to increase the supply of blood in the genital organs The ovarian treatment apparently exerts a local action on the ovaries themselves, as evidenced by more regular menstruation It might also influence growth processes in the uterus and tubes, and thus improve the hypoplastic infantile conditions A tonic action on the general health can usually be relied on Bab advises discontinuing the ovarian treatment after conception has occurred

Fellenberg has found treatment of sterility along these lines effectual in a number of cases In one particularly instructive instance pulmonary embolism and pleurisy had followed the first childbirth and there had been lassitude and headaches during the seven years since with no conception The entire system had evidently been exhausted and the genital functions in particular Under ovarian medication and courses of spa treatment, with hot vaginal douches and sitz baths, the general health improved and the genital functions became normal The woman now has four children

Thyroid treatment may be indicated in certain cases of sterility Among the signs of thyroid insufficiency are the abnormally rapid coagulation of the blood, relatively small neutrophil and high lymphocyte count, such women are inclined to be nervously irritable, with a tendency to spastic constipation and sick headache Sehrt goes so far as to declare that an infantile uterus always suggests thyroid insufficiency With hypofunctioning on the part of the thyroid conception may occur, but abortion follows almost at once Fellenberg has given thyroid treatment for habitual abortion, and it has been successful in a number of instances The blood count must be supervised with special care during the thyroid treatment, examining the blood picture anew every two weeks at least In the cases in this category, women long sterile became pregnant, the tendency to spastic constipation subsided, and the general health improved, while the blood picture returned to normal Weil has also noted progressive improvement in the functioning of the genital organs under thyroid treatment Gross and Tandler have reported that the thyroid was found abnormally small in persons who had been castrated Others have called attention to the elective dilatation of the vessels in the thyroid and the lower pressure in them under the influence of ovarian treatment There is thus much evidence on hand testifying to the reciprocal influencing of the thyroid and the genital organs, and this fact can be utilized to stimulate defective functioning of the latter

Deutsche medizinische Wochenschrift, Berlin

59 **Ventricular Fibrillation Main Factor in Sudden Death in Angina Pectoris**—Obstruction of the coronary arteries, in connection with other factors, is liable to induce ventricular fibrillation The predisposing factors are the size of the artery, the functioning of the area it nourishes, general anesthesia, hemorrhages, and trauma in the vicinity The direct exciting factors may be listed in order of importance as the local ischemia, local action of toxins, carbon dioxid in particular, and, finally the heterotopic impulse, that is, the abnormal impulse to uncoordinated contractions of the fibers of the ventricle walls The abnormally located impulse for the wave of contraction is the immediate precursor of the fibrillation for we know that this is the consequence of the highest degree of heterotopic impulse production (*heterotope Reizbildung*) The direct actual proof that the sudden death in angina pectoris is the result of ventricular fibrillation can be supplied only by electrocardiography And as death occurs instantaneously, it may never be possible to apply this method of examination unless chance intervenes But if this testimony could be once produced, it would demonstrate that the individual does not die from paralysis of the heart but from the direct opposite, the excessive production of impulses This knowledge would give us the clue to prevention and treatment, as we would seek to ward off everything that might favor heterotopic impulse production Even if we knew only that angina pectoris is a symptom of heart disease, the extreme suddenness of death, without anatomic findings, could be explained only by fibrillation of the ventricles But we already have data which show that angina pectoris occurs only when there is temporary ischemia of the heart, and we know by experiments on animals that this ischemia is liable to precipitate fibrillation of the ventricles and also that the ischemia predisposes the heart to fibrillation Hence even the pathogenesis of angina pectoris sustains the assumption that death is the result of ventricular fibrillation (*Herzkammerflimmern*)

63 **Artificially Induced Fever Temperature in Treatment of Gonorrhea**—As the gonococci are killed so easily by temperatures of only 42 C (107 6 F), attempts have often been made to sterilize the urethra by application of heat But the constant influx of blood keeps the temperature below the required degree of heat, and all such attempts have proved futile to date Weiss solves the problem in another way, by keeping the patient in a hot bath until the entire body is heated to the required fever temperature In eleven cases of recent gonorrhea he had the men take a hot bath forty or fifty-five minutes long, with the temperature of the water gradually increased from 40 to 43 5 C (104 to 110 5 F) In one case the body temperature was raised to 42 6 C (108 5 F) in a forty-minute bath and the gonococci disappeared entirely at once In the other cases the body temperature did not go so high, but the vitality of the gonococci was evidently reduced and under a few local injections they soon all disappeared

69 *Diagnostic Importance of Occult Hemorrhage in Gastro Intestinal Tract. (Om smygande blödningar inom matsmaltningskanalen) L Wolff

69 Occult Gastro-Intestinal Hemorrhage—Wolff gives the detailed history of the study of occult gastro-intestinal hemorrhage to date, and emphasizes the diagnostic importance of positive findings provided no meat has been eaten for the few days preceding He emphasizes further the marked tendency to heal of a solitary gastric ulcer, which renders persisting occult hemorrhage so significant He also comments on the necessity for strict regulation of the diet after operations on the digestive tract He regards testing for occult hemorrhage as an indispensable routine procedure in all dubious cases, at least in all dubious stomach cases In his own recent practice the positive and also the negative findings in a number of cases gave the clue to the real source of the trouble, confirmed by the later course of the cases The value of the test was shown particularly in a case of severe anemia with hemoglobin below 50, but no symptoms on the part of the digestive tract except occult hemorrhage In another case there was intense cardialgia and gastric ulcer was assumed, but no benefit followed treatment on this basis and no occult hemorrhage could be detected On this negative finding, treatment for syphilis was instituted and prompt recovery followed In another case anemia and nervous symptoms on the part of the stomach were assumed at first to be a recurrence of a gastric ulcer which had been successfully treated ten years before The constantly negative tests for occult hemorrhage apparently excluded gastro-intestinal trouble, and under general tonic measures health was soon regained In a case of chronic hyperacidity with pains, vomiting and emaciation, the absence of occult bleeding excluded cancer, and no trace of malignant disease was found at necropsy In gastric ulcer cases the improvement under treatment could be followed in the subsidence of the occult hemorrhages Occult hemorrhage also revealed in some cases the presence of malignant disease in the stomach before there was any tumor or debility, and in many dubious cases turned the scale one way or the other, and always reliably, according to Wolff's experience to date

70 *Three Cases Illustrating Connection between Diabetes Insipidus and Functioning of the Hypophysis Cerebri K Motzfeldt.
71 *Action of Hypophysis Extracts on Diuresis, Blood Pressure and Nitrogen Metabolism in Fifteen Relatively Healthy Subjects. (Studier over hypofyseekstrakters virkninger —særlig paa diurese, blodtryk og N Omsætning, hos relativt friske mennesker) K Motzfeldt
72 *Orthostatic Albuminuria and Its Relation to Nephritis P F Holst

70 Diabetes Insipidus and the Hypophysis Cerebri—Motzfeldt's article is an able summary of the literature on this subject to date, with detailed reports of three cases of diabetes insipidus In none of them could anything abnormal be discovered in the hypophysis, but a number of symptoms pointed to insufficiency of the posterior lobe of the pituitary body Marked benefit followed treatment with an extract of this lobe From five to seven beef pituitary glands had to be eaten at a time, Motzfeldt says, to obtain an effect even approximating that of one-fourth of a syringeful of the commercial extract

He knows of no case on record in which pituitary treatment was applied so systematically and so perseveringly as in one case here described No other measures had any effect except that opium slightly reduced the diuresis, probably by the diminished thirst This patient is a trained nurse of 42 The diabetes insipidus developed in 1913, with diuresis of from 8 to 10 liters She increased 20 pounds in weight, and menstruation ceased, with increasing lassitude The intake and output of fluids, the specific gravity, the proportional elimination of chlorids and of nitrogen and the total amount of the latter eliminated are recorded day by day during three months under treatment with an extract of the posterior lobe of the pituitary body The benefit from it was manifest, less urine was voided and the patient felt better Treatment was then continued with pituitary substance obtained fresh from the slaughter-house each day The beef glands were sliced and cooked or eaten raw or dried She thus took from two to seven each day and finally took seven every second evening on retiring Under this treatment she sleeps quietly all night, is not tormented by thirst, has lost 2 pounds, and feels perfectly well, while menstruation has returned One of the tables shows the effect of hypophysis treatment on the concentration of the urine It was given every two hours, and the urine was examined at corresponding intervals The density ran up at once from 1,004 to 1,014 and reached 1,017 after the fifth subcutaneous injection of 0.5 c c of the extract

The extract of the anterior lobe did not seem to influence the diuresis, and neither extract seemed to affect the elimination of nitrogen In the second case, the patient a woman of 23, the diabetes insipidus developed after chicken pox at the age of 10, and had persisted for thirteen years The general aspect suggested Lorain's "hypophyseal dystrophy" The third patient was also a woman, now 39 Cerebrospinal symptoms of syphilis during the last four years suggest that the diabetes insipidus, installed for the last six months, may owe its origin to some gummatous process in or encroaching on the posterior lobe of the pituitary body The visual field was normal in all the cases, and roentgenoscopy of the base of the skull revealed nothing abnormal Motzfeldt suggests that cases of primary polydipsia should also be examined for pituitary insufficiency

71 Influence of Hypophysis Extracts on Metabolism—In the fifteen relatively healthy persons tested, an extract of the posterior lobe reduced the output of urine and increased its concentration, but the elimination of nitrogen did not seem to be affected

72 Postural Albuminuria in Relation to Nephritis—Holst examined postmortem the kidneys of a youth of 16 who had had typical orthostatic albuminuria during the last five or six years but had beeen otherwise normal until he contracted galloping tuberculosis of the lungs Not a trace of inflammation could be discovered in the kidneys, notwithstanding the years of pronounced postural albuminuria He cites further a number of clinical cases all confirming the same, namely, that this postural albuminuria may in some cases be of purely functional nature Hence it is irrational and may be positively injurious to treat a person with postural albuminuria as if he had actual kidney disease He reports from his hospital service ten cases in which the orthostatic albuminuria was a chronic condition but no tube-casts were ever found in the urine Several of these patients had been sent to the hospital for assumed nephritis and had been treated for this In five other cases there was pronounced orthostatic albuminuria but at the same time the presence of tube-casts, high blood pressure and increased area of dulness over the heart indicated nephritis In the first group there seems to be no tendency to actual nephritis, but such patients generally need tonics and general building up to aid them in outgrowing the tendency to postural albuminuria Of the fifty persons with postural albuminuria he has encountered, two have died of tuberculosis

TROPICAL SANITATION IN ITS RELATION TO GENERAL SANITATION *

W C GORGAS, M D
Surgeon General United States Army
WASHINGTON, D C

As this evening I am speaking to health officers, I shall dwell more particularly on matters which have forced themselves on my attention during a lifetime spent in most active health work From long experience, certain convictions have been gradually forced upon me as basic in all health work These basic facts have not been generally recognized, as far as my experience goes To make my argument clear, I shall run briefly over my own experience in this field

The great awakening in tropical sanitation which has taken place in the last twenty years began with the Spanish-American War For the last three or four hundred years it has been known by Europeans that military expeditions involving any large bodies of white troops could not be undertaken in the tropics on account of the great loss from disease In the many cases in which such campaigns had been undertaken, they had failed on account of the loss of life caused by, and the disability due to, tropical diseases These tropical diseases in the Western hemisphere were chiefly yellow fever and malarial fever

It is astounding to the military sanitarian of the present day to read of the losses caused by yellow fever to military expeditions in the West Indies One can hardly believe the loss reported as possible The English Army in the Windward Islands in 1794 under Sir Charles Grey, out of a total strength of 12,000 men, lost 6,000 The French Army in Santo Domingo in 1798, out of a total strength of 25 000, lost over 22,000 from yellow fever Again in 1802 the French Army in Santo Domingo, out of a total strength of 40,000, lost 20,000 Where it prevailed it was equally fatal to civil populations Yellow fever has many times ravaged the United States, and still more severely affected Spain In 1798 Philadelphia, out of a population of 20,000 inhabitants who remained in the city, lost 4,000 New York City, out of a population of 50,000 in 1798, lost 2,500 New Orleans, out of a population of 100,000, lost, in 1853, 8,000 of its citizens Spain in 1800 lost 60,000 people from yellow fever, and again in 1804, 50,000 Barcelona in 1821, of a population of 70,000, lost 16,000 Gibraltar in 1804, with a population of 10,000, lost 6,000

These figures give some idea of the disease in its bad form Yellow fever, like syphilis, was an American disease and was not known to Europeans before the discovery of America by Columbus The severity of yellow fever is such that it has prevented successful colonization by Europeans in countries where it can become endemic

About the beginning of the nineteenth century it looked as if yellow fever was about to spread over the whole known world If the manner in which yellow fever became epidemic in Spain is any measure of the manner in which it would affect China and India, some idea of these conditions can be imagined About the middle of the nineteenth century the area affected by yellow fever began to decline, and it has since then continued to contract till at the present time it has almost become extinct

All during the nineteenth century the United States was so frequently ravaged by epidemics of yellow fever, and so great loss of life and loss of wealth had been thereby brought about, that the people were willing to go to great expense or submit to drastic measures for the purpose of getting protection from the disease It was very evident to sanitarians who had given any study to the matter that the epidemics which affected the United States were imported from the endemic focus, which had existed at Havana, Cuba, for the preceding 150 years The United States was, therefore, very anxious to get rid of Havana as an endemic focus

When we came into possession of this city in 1898, as a result of the Spanish-American War, every endeavor was made by the authorities to eradicate yellow fever The whole attention and force of the government were centered on the effort to clean up the city Yellow fever was then believed to be the best example of a disease caused by filth In 1900, two years after our occupation, Havana was one of the cleanest cities in the world But yellow fever was worse than it had been for several years I, at this time, was health officer of the city under the military governor The authorities were at their wits' ends and knew not what to try The Cubans were very much inclined to poke fun at us and at our extraordinary ideas on the subject of sanitation

I one day overheard a conversation on this subject between a Cuban man and his wife A large tenement-house had been emptied of its inhabitants for the purpose of cleaning and disinfecting The families were sitting around on their household goods in all degrees of discontent and irritation Both husband and wife criticized the eccentric Americans very freely The wife began to advance some extenuating circumstances — that after all the cranky Americans would leave their house clean and free from bugs The husband took the ground that the Americans had a

---

* Address delivered at the Fifteenth Annual Conference of Health Officers of New York State at Rochester Sept. 6 1915

right to be as cranky and clean as they wished as long as they applied it to themselves, but when they attempted to force their crankiness and their cleanliness on free-born Cubans things had gone entirely too far

The Havanese population as a whole were very patient under our rigid sanitary measures I shall always remember with kindness and affection their good natured attitude toward the sanitary department during the four years I spent in their midst as health officer of the city

A distinguished physician of Havana, Dr Carlos Finlay, had been maintaining for the previous twenty years that yellow fever was conveyed from man to man by a certain species of mosquito, the stegomyia From the known facts with regard to yellow fever and from the life history of this species of mosquito, Dr Finlay had reached this conclusion by a most logical and interesting argument Dr Finlay has died in Havana within the last month at the ripe old age of 82 He is one of the great men in medicine who lived long enough to see his work recognized

The army board, consisting of Reed, Lazear, Carroll and Agramonte, took up in 1900 the investigation of the question of the transmission of yellow fever by the mosquito They carried to conclusion one of the most mathematical demonstrations ever accomplished in medicine They placed men out in the country near Havana, so guarded that it was impossible for them to contract yellow fever from their surroundings They then took the female stegomyia mosquito, allowed her to sting men sick with yellow fever, and then bite the men in this camp The men bitten developed yellow fever They then took material soiled by yellow fever patients in every possible manner, had men sleep in rooms filled with this material for weeks at a time No one contracted yellow fever in this way They took the blood of yellow fever patients and injected it into well men They developed yellow fever They took the blood of a yellow fever patient and passed it through a filter that would stop any particle large enough to be seen by a microscope of the highest power This filtered blood, when injected into the circulation of a well man, still gave yellow fever They heated the blood of a yellow fever patient and then injected it into the circulation of a well man The man did not develop yellow fever They took the blood of a yellow fever patient who had developed yellow fever as the result of the hypodermic injection of blood from a preceding yellow fever case This blood caused yellow fever in the man into whose circulation it had been injected This board, as the result of their labors, published the following very important conclusions

Yellow fever is conveyed from man to man by the bite of the female stegomyia mosquito, and, in Nature, is probably conveyed in no other way The disease is not conveyed by fomites of any kind The disease is transferred by a parasite circulating in the blood and not by a toxin This parasite is too small to be seen by the highest powered microscope then in use, and is killed by being heated The parasite lives in the blood of the patient only during the first three days of the disease, and, therefore, the mosquito can be infected only during that time It takes from twelve to twenty days for the parasite to go through its development in the mosquito and pass from the stomach to the salivary glands of the insect Therefore, the mosquito is harmless for the first twelve days after biting the man sick of yellow fever

The sanitary department of Havana took these important announcements of this board, and worked out the measures whereby they might be made of practicable effect in our fight against yellow fever We established a quarantine whereby all infected ships or persons coming into the harbor of Havana were cared for, and a system of inspection whereby all such persons coming in by land were looked after Our inspectors also saw daily at Panama every individual liable to yellow fever A yellow fever patient was so screened and cared for that the stegomyia could not bite him The attempt was made to kill by fumigating all mosquitoes that might have become infected from each case And, finally, the attempt was made to destroy all mosquito larvae breeding anywhere within the city limits

In the long run we found the destruction of the larvae to be a measure of more importance than all the other measures put together

We commenced our antimosquito work at Havana in February, 1901 The last case of yellow fever in the city occurred in September of the same year Havana had been the great endemic focus of yellow fever for all the Northern hemisphere during the preceding 150 years Since the extinction of yellow fever in Havana, fourteen years ago, this disease has practically disappeared from the Northern hemisphere

In 1898 Sir Ronald Ross of the English army had demonstrated that malaria was conveyed from man to man by another species of mosquito, the anopheles He and other workers had established much the same condition as to the transfer of malaria as I have just described with regard to yellow fever It was evident to the sanitary authorities, therefore, that a very slight extension of the work against yellow fever ought to cover work against malaria This has turned out to be the case Malaria rapidly decreased with the inauguration of the antimosquito work, and has since become practically extinct

In 1904 our government undertook the construction of the Panama Canal On account of the success of the work at Havana, I was placed in charge of sanitation at Panama I succeeded in getting a good many of the men who had acquired experience in the work at Havana to come to Panama These men were of inestimable value not only in the active organization of the work, but also in stemming the tide of fear, discouragement and hopelessness which existed on the isthmus during the first two years of our work there Many of you here can understand what a moral support it is to a health officer to have twenty-five or thirty loyal men behind him These men had been through similar work at Havana and knew that we were bound to succeed if we could only hold on long enough and convince our superiors that we were on the right track But for a period in 1905, when yellow fever was at its height, we found ourselves working among a panic-stricken population who believed that we were cranks and fools Our superiors on the isthmus at this time had become affected by the prevailing panic and were reporting to the authorities at Washington that our work had failed and were asking that we be relieved, and that men more practical and sane replace us

This report would have ended sanitary work at Panama along the lines of modern tropical sanitation had it been acted upon

For two years succeeding this time we were given the loyal support of our superiors, and by the middle of 1907 the work was accomplished The request for our dismissal was made by the commission in June, 1905 In September, 1905, the last case of yellow fever occurred in the city of Panama, and only one case has occurred in the Republic of Panama since that time All health conditions rapidly improved, and soon the isthmus, as to health, would compare favorably with many parts of the United States

The eradication of yellow fever and the control of certain other diseases was undoubtedly due to the special sanitary measures taken against these diseases But these special measures could have had no effect on the general health conditions For the last fifteen years I have given a great deal of thought to this matter What did we do at Havana and Panama to cause the great general improvement in health conditions which took place shortly after our arrival at both places, and has since continued?

At Panama shortly after our arrival we increased the wages of the common laborers from 11 cents an hour to 20 cents an hour This was nearly four times the wages of the laborers in the surrounding countries He knew that every fourth man would die each year of diseases prevalent on the isthmus, and it took strong inducements to get him to come at all

If we paid the citizen of a foreign country four times the wages he got at home, we naturally had to increase largely the pay of American citizens whom we wished to get to come to the isthmus This caused a steady increase in wages all along the line During 1904 and 1905 this increase of wages was going on all the time Every time a prominent official died of yellow fever it would cause a stampede in the force We would have to offer inducements to get the old men to come back and to get new men to come in the places of those who would not come back for any inducements If yellow fever had continued, we would still be raising wages on the isthmus This large increase in wages caused a great general improvement in all living conditions — more room to live in, better food and better clothing I am satisfied that to this improvement in social conditions, caused by our high wages, we owe principally our extraordinary improvement in general health conditions It is a health officer's duty to urge forward those measures in his community which will control individual diseases, but my long experience has taught me that it is still more his duty to take that broader view of life which goes to the root of bad hygiene, and do what he can to elevate the general social conditions of his community This, my experience has taught me, can best be accomplished by increasing wages Such measures tend at the same time to alleviate the poverty, misery and suffering which are occurring among the poorest classes everywhere in modern communities At Panama we increased wages by edict of the government But our government got this money by taxing the people of the United States It would have been of little benefit to our laborers if we had increased their wages by 10 cents an hour and then taxed them by 10 cents an hour in order to raise this money

Such would be the result in the United States if we attempted to increase wages here by edict of the government as we did in Panama Such increase would be of no benefit to the laborer

Natural, just and proper wages are just what each man produces, not a cent more or a cent less We can look back in the history of our own country and see that this condition of affairs was approximated in the early settlement of the country A man coming to this country would take up land for which he paid nothing, and his wages were all he produced on that land After a while all the land is taken up and the next man who comes has to work for some one else Later a great many more men come, and these men bid against each other for work, and thus force down wages This has gone on in the United States, and in all other civilized countries, till at the present time all producers get much less than natural wages, that is, what they produce

Can this unfortunate and undesirable condition of wages be rectified?

Suppose an area of land as great in extent, and as fertile in production as the present Mississippi Valley, should tomorrow rise from the bottom of the Atlantic Ocean off the coast of Long Island Suppose the United States should own this island and offer it to its citizens under our present homestead laws Thousands of the citizens of New York would flock there and take up this land These wages would be natural wages Each man would get all that he produced this would be very much in excess of the wages now given in New York All the poverty, sickness and degradation caused at present by low wages would be rapidly ameliorated The man who was so fortunate as to be appointed health officer for this island would in a few years be able to publish the most astounding health reports

It is entirely possible for us to raise from the bottom of the sea just such an island as I have described In every town and county in New York a large part of the lands are unused or only partially used If this large body of unused land could be brought into use, the effect on the health conditions of New York would be exactly the same as would be produced by raising the island I have described

Can these unused lands be brought into use? If these unused lands were taxed to such an extent that the owners would have to use them to the fullest extent in order that they might pay the taxes, is there any doubt as to what the result would be? All unused lands would soon be utilized to their fullest extent The only way of making any profit from them would be to so use them It would be a very losing venture not to use them to their fullest extent

I have been fortunate enough to labor as health officer in a field in which very great health results have been produced, but they would be small as compared with the health results which will be produced by securing for mankind natural wages It stirs my enthusiasm to think of what glorious opportunities are before the young health officer just commencing life I have spent my sanitary life killing tropical mosquitoes, and I hope have thereby benefited my fellowman I would give a good deal to spend another sanitary life in the ranks of the coming generation of health officers doing my share in the fight that is on us, the fight for the greatest of all sanitary measures, natural wages

---

Health, Social Service and Government.—The higher ethical standards and the broad humanitarianism which have developed among large masses of the people, in these recent years demand that the health and socal service activities of the government shall be absolutely divorced from politics — Governor Charles S Whitman of New York.

THE HANDWRITING ON THE WALL*

TORALD SOLLMANN, M D
CLEVELAND

In the recent convention of the National Wholesale Druggists' Association, Mr H A Hover of Denver, chairman of one of the committees, referred to the subject of "proprietary" and "patent" medicines in the following words [1]

> I apprehend that sooner or later we will all be up against not only radical state legislation, but national legislation as well, and we might as well forestall drastic action and lend a guiding hand as to the character that legislation shall take on We did it properly and successfully in connection with the legislation on narcotics, and we might as well see the handwriting on the wall in this case
>
> This is an important question, which involves over 50 per cent of our business, and we do agree that there are certain abuses incident to the manufacture and distribution of proprietaries which have grown up and which involve a lot of remedies that we cannot consistently defend, and we might as well lend our aid and start to clarify the situation

It is gratifying that the handwriting should be perceived by important commercial bodies — for the "patent medicine" business is, unfortunately, largely a commercial question

This awakening of the drug trade to the "patent medicine" evil is a most welcome accession to the forces that are working for the protection of the people In the past, it is true, individual voices have been heard in protest, but for many years the drug trade, wholesale and retail, has winked at these evils Too often it has even encouraged them The "patent medicine" business could never have reached its present vast proportions had it not been backed by the silent, and very often by the voiced recommendation of the drug trade These proportions are, indeed, enormous Mr Hover presents statistics showing that proprietary and "patent" medicines constitute over half of the total sales of the wholesale druggist — a little more than all the standard drugs, sundries, appliances and the multitude of things that go to make up the stock of the ordinary drug store The Commission on Proprietary Medicines of the American Pharmaceutical Association, in a report presented this year,[2] estimates that the number of "proprietary medicines" on sale in the United States is from 40,000 to 50,000, exclusive of any "own make" preparations with only local reputation

While the drug trade has been a partner in the growth of this business, and must take its share of responsibility for the abuses, it should not be blamed unduly Many of the evils arose insidiously and were practiced thoughtlessly It is more profitable and more just to rejoice that the conscience of the trade is now awakening, and to extend every aid in the power of our profession to make this awakening effective In particular, we should give credit to the American Pharmaceutical Association for bringing the issue squarely before the pharmacists It remains to be seen whether the association and the pharmacists will follow up this first step whether they are ready to lay the ax to the root of the evil, whether they intend merely to prune a few of the overluxuriant branches, or whether, finally, they will prefer to shut their eyes and minds to the logic of events, and let things drift

Their problem is not an easy or simple one At the first view, it might seem that they had a final remedy in their power They need only refuse to handle "patent medicines," and these would practically go out of existence So drastic an action, however, would not be supported by present public opinion The very fact that these medicines have so large a sale shows that the public wishes to use them, and that the public must first be educated to their evils, before it will wholeheartedly countenance their suppression In the long run, more can be accomplished by fighting against the specific evils of the "patent medicines," than by attempting to suppress "patent medicines" as a class

The drug trade is wisely choosing this path, if its attitude is fairly reflected in the report of the American Pharmaceutical Association commission already referred to This starts with a study of the various detailed problems involved On the basis of this study, the commission has drawn up a set of provisional rules as minimum requirements for an honest "patent medicine" All of these are in the right direction A frank critic, however, must concede that they scratch only the surface of the evil, and promise only a slight palliation, and not a cure The real cause of the evil is only very lightly, one might even say rather tenderly, touched on by the commission, but a further report is promised, and it is to be hoped that this will deal with the fundamental matters more frankly Yet the present report contains interesting material, and deserves careful reading in the original Its main features, however, may be abstracted and discussed

The commission first points out some of the weak points in the stock arguments against "patent medicines"

1 There is a contradiction in the claim, on the one hand, that "patent medicines" are nothing but everyday prescriptions — on the other hand, that they are dangerous and worthless Their defenders are prompt to inquire "why a given mixture should be considered a valuable and efficient remedy when dispensed by or on the order of a physician, and dangerous and worthless when put up in a carton with a printed label and wrapper"

The contradiction is of course easily answered, in fact, the commission furnishes the answer under 4, below

2 So far as pharmacists are concerned, it is pointed out that the condemnation of widely advertised "patent medicines" looks insincere when they recommend their "own make" preparations of similar character They do, indeed, defend the latter as being "nonsecret" In fact, however, their composition is not often divulged to the purchaser It might be added that "own make" preparations really conflict with the tendency of medical practice acts, and will eventually have to disappear when these acts are consistently framed and applied For "own make" preparations would have practically no sale unless they were personally recommended by the vender, and the personal recommendation of drugs is nothing more or less than prescribing

3 While disclaiming against proprietary medicines as a class, pharmacists have not hesitated to stock and sell them, and often to recommend them, individually Physicians who own drug stores have not been any more consistent

[1] Forty First Annual Meeting of the National Wholesale Druggists' Association, stenographic report, in Oil, Paint and Drug Reporter, Oct 7, 1915, p 37

[2] Report of the Commission on Proprietary Medicines of the American Pharmaceutical Association, Jour Am Pharm Assn, October 1915, p 1148

4 Only minor emphasis has been placed on what the commission rightly considers the greatest evil of the "patent medicine" industry, namely, "the falsity and extravagance with which its products have been exploited" Every one must agree with the commission, that "this is the basic evil of the 'patent medicine' business and the point where it is most vulnerable, and an attack upon this evil needs no argument for its justification"

The commission goes on to say, "Numerous 'patent medicines' are mixtures which have some merit if properly applied in cases for which they are adapted, the evil is not in the remedies themselves but in the method of their exploitation"

This also is true as a theoretical proposition The question that the drug trade itself must attempt to answer is precisely this *Can "patent medicines" be properly exploited?* If so, how?

The commission next takes up the distinction between "proprietary" and "patent" medicines This distinction, it rightly concludes, depends essentially on whether or not the drug is advertised to the lay public, directly or indirectly A medicine that is so advertised is a "patent" medicine, while one that is advertised only to physicians is a "proprietary" medicine The commission points out that if advertising to the laity were prohibited absolutely, the use of proprietary medicines, except under the direction of qualified physicians, would be reduced practically to zero

The commission considers that the problems of proprietary drugs are being properly and sufficiently cared for by the Council on Pharmacy and Chemistry, and that there is no call for the pharmaceutical profession to invade this field

The commission then goes into an extensive consideration of the various questions involved in the "patent medicine" problem On the basis of this, it formulates a set of tentative declarations of minimum requirements which "patent medicines" should meet in order to render them safe in the hands of the general public It is emphasized that these are only provisional and subject to modification These rules are so important that it seems worth while to reproduce them, together with some critical and constructive comments

MINIMUM REQUIREMENTS

1 *Prescription Fakes, Concealment of Proprietary Character*—The preparation must not be named or advertised in such a way as to conceal its proprietary character and lead the purchaser to believe that it is a *simple chemical or vegetable drug* ordinarily purchasable in small quantities instead of a proprietary mixture or substance

This is a protection against a common form of fraud The rule may be endorsed as it stands

2 *Methods of Marketing*—The preparation must be one which is regularly offered to the public through the usual trade channels, i e through regular wholesale and retail dealers in ready-made medicines, and thus subject to inspection by the authorities charged with the enforcement of state food and drug laws

This would facilitate official supervision, especially of intrastate trade, by restricting the sale of medicines to licensed dealers

This will become of material benefit to the public, however, only if these dealers are made legally responsible for their merchandise, for instance, for any misrepresentation, damage caused by the medicine, etc Mere "inspection" will not furnish much protection

With this proviso, the rule may be indorsed

3 *Alcohol Content*—If the preparation contains alcohol, it must be sufficiently medicated to prevent its use as an intoxicating beverage, and in addition to this requirement, the proportion of alcohol present must not be greater than is properly necessary to hold in solution in permanently active condition the essential constituents of the preparation, and to protect the preparation against freezing, fermentation, or other deleterious change

This aims to prevent the use of "patent medicines" as intoxicants As stated in another part of the report, "it seems fair to assume that when the alcohol percentage of a mixture is far in excess of pharmaceutical requirements, it is for the express purpose of making a preparation that will serve as a substitute for beverage liquors"

The rule, however, does not go far enough really to protect the public The present internal revenue regulations cover practically the same field, but they have undoubtedly failed to abolish the abuses This is easily understood, for it is impossible to lay down any hard and fast line as to when an alcoholic medicine is "sufficiently medicated to prevent its use as an intoxicant" No one doubts that medicines containing merely vegetable extractives, such as many bitters, tonics, female remedies, etc, are often taken as intoxicants, even when the consumer does not realize this If they produce the effects of alcohol, they are intoxicants, even when they are not used to the extent of paralyzing the victim

There is but one way of doing away with the abuse of alcohol under the guise of "patent medicines," and that is to prohibit absolutely its sale to the public in this form, for the manufacturer, since he does not know the consumer, cannot guarantee that his alcoholic preparations will not be abused intentionally, or that it will not create an alcohol habit

The rule in its present form sounds well, but to accomplish its professed intent, it should read, "No preparation may contain alcohol"

4 *Content of Habit-Forming Narcotic Drugs*—If the preparation is one which is capable of being used internally, whether recommended for internal use or not, it must not contain cocain nor shall it contain opium or any of its alkaloids or their derivatives, in greater proportions than those specified in Section 6 of the federal law commonly known as the Harrison Act, and it shall also contain other active drugs in such proportion that the use of the preparation will not be likely to create a drug-habit, nor satisfy such a habit when previously existing

This provision is well meant, especially the last clause, that any preparation containing a habit-forming drug must also contain other active drugs in such proportion as to make its use for satisfying the drug habit impossible However, the same insuperable difficulty exists here as in the case of alcohol, namely, that it is impossible to draw a definite line The way to abuse is still open, the occasion still present, just as it is in the Harrison Narcotic Law Are not the frightful dangers of the opium habit greater than the possible benefits of the direct sale of opiates to the public—however much one may try to guard against these dangers? Is it really indispensable to the welfare of the public that disguised opiates should be on sale? What ailments are there that are really benefited by amateur treatment with opiates, and that could *not* be benefited as much or more in less objectionable ways?

5 *Remedies for Children's Use*—If intended for administration to infants or children the preparation must not contain cocain or opium or its alkaloids, or their derivatives in any proportion whatever

This merits unqualified indorsement The only criticism is its restriction to infants and children It should read "The preparation must not contain cocain, opium, etc , in any proportion whatever "

It may also be pointed out that Rule 5 would furnish little protection to children, so long as the sale of opiates, etc , is permitted by Rule 4 The same cough syrups, etc , are used for all ages

6 *Activity of the Preparation, Cautions Against Misuse*—The preparation must be of such character that it will not be liable to endanger life or health when used in accordance with the accompanying instructions, and if the preparation is one which is liable to occasion injury when improperly used or when used to excess, the accompanying literature must bear instructions tending to guard against such improper or excessive use

This provision is intended to diminish the danger from toxic constituents It may be indorsed, with the important addition, "All preparations which may occasion harmful effects, even when used improperly, must be plainly and conspicuously labeled POISON "

7 *Immoral or Illegal Purposes*—The preparation must not be intended for use as an abortifacient or for use for any other immoral or illegal purpose, nor must it be advertised or recommended either directly or indirectly as an abortifacient or for any immoral or illegal purposes

The advisability of this rule is self-evident

8 *Incurable and Contagious Diseases*—The preparation must not be advertised or recommended as a cure for diseases or conditions which are generally recognized as incurable by the simple administration of drugs, or for the cure of contagious or acute diseases the treatment of which properly requires the supervision of a qualified medical attendant

This is the only rule to which the National Wholesale Druggists' Association took exception It is stated in the stenographic report that the reasons for their adverse action will be transmitted to the commission, and it will be very interesting to have these published On its face, the rule seems perfectly fair, and to the public interest Theoretically, it is of course conceivable that some one might discover a drug cure for an incurable disease, and market this as a "patent medicine" Practically, the contingency is too remote for serious consideration If such a discovery were actually made, the inventor should be required to prove that he has found a cure, and if he succeeded in doing so, the disease would no longer be incurable, and his medicine would therefore not come under the provisions of this rule Experience has shown, however, that the requirements for this "proof" should be extremely stringent The rule deserves indorsement as it stands

9 *Conformity to the Federal Food and Drugs Act*—Neither the label on the package nor any of the accompanying literature shall bear or contain any statement in conflict with the misbranding provisions of the Federal Food and Drugs Act.

This is self-evident

10 *Advertising Not Accompanying the Package*—Advertising not accompanying the package shall conform substantially to the statements on the label, carton, or in the accompanying circulars as to the origin, composition or character of the preparation, or concerning its curative or remedial value

This rule is needed to check irresponsible advertising in the newspapers, circulars, etc , which are not readily reached by the present machinery of the law The rule deserves indorsement, but the chances are that it would not be enforced, unless a rather elaborate machinery of supervision were provided

THE SECRET FORMULA

Taking the rules as a whole, as they stand, there can be no doubt but that their enforcement would correct some of the flagrant "patent medicine" evils As has been indicated, they could be modified so as greatly to increase their efficiency Even then, however, they are merely so many plasters to the sore, and as with all kinds of superficial treatment, when we succeed in healing the sore in one place, it is apt to break out in another, until the disease itself is attacked It is questionable, therefore, whether we are not simply wasting time by experimenting with legal plasters, instead of attacking the fundamental fault What, then, is the spring of the "patent medicine" evil? Why is it that the makers of "patent medicines" have been able to deride all past efforts to correct their abuses? Why has it been possible for them to make exaggerated and false claims, such as could not be made in any other line of business? Why have they been able to sell poisons, to foster alcohol and drug-habits, to create imaginary disorders and to prevent the treatment of real diseases, to injure individuals and the community in health, happiness and purse? Why have they been beyond the efficient reach of law and of public opinion?

If the commission seeks a true answer to this question, it will find it in a single word, and in nothing else *secrecy* Until this is corrected, all rules and laws are more or less futile So long as the composition of "patent medicines" is secret, it is impossible to make them subject to any efficient law So long as the composition is secret, the manufacturer has every technical advantage—he is working in the light, the public in the dark You may, it is true, try to meet his older tricks, one by one, you may succeed in making him name his poisons, narcotics or alcohol, you may even prohibit them—provided they are such as you can succeed in isolating from his complex mixture You may legislate against his selling harmful preparations or making untrue claims, but to apply the law, you must prove your contention Here secrecy is a strong, often perfect protection, for to prove the harm or disprove the claims of a complex mixture of unknown composition is a task of such magnitude as to frighten the average prosecutor out of the attempt It would tax the resources of a large scientific and legal institute to bring a dozen of the plainest offenders to task, each year—the thousands of other offenders meanwhile basking in immunity And then, the offender having paid his fine out of a day's or week's profit, need only spend five minutes in making up a new secret formula—and where is the profit to the public?

On the other hand, assume the composition published, and the task of the inspectors becomes, relatively, a pattern of simplicity The composition can be checked, chemically, with infinitely greater ease, when the supposed ingredients are published The claims can be checked much more simply when one can utilize the large amount of data that science has accumulated The "patent medicine" business can be made to travel, as any honest business, on its merits, instead of its imagination

The secret formula, then, is the key to the "patent medicine" evil The commission does not appear to have perceived this clearly, at least, it has not made up its mind It states that it is "by far the most delicate and difficult” phase of the subject — doubtless so, because it is the crux of the situation — and wisely wishes to make sure of its ground before announcing a conclusion. The conclusion will be awaited with great interest, for by it the report of the commission will stand or fall, by it the thinking public will decide whether or not the commission places the public welfare above all other considerations.

There are at present three plans of dealing with the formula question. The first, to permit the manufacturer to keep the ingredients secret, as at present, except for certain specifically stated poisons. Second, the confidential registration of the formula with some government commission, this is the plan in force, or proposed, in England, Canada and New York City. Third, the publication of the formula on the label. By the latter is commonly meant the statement of the active ingredients and their quantities, without requiring the details of the working formula, flavors, menstruum, etc.

The arguments which are made by the opponents of the published formula are, that this would amount to confiscation of the property, that it would do no good to the consumer, and that the formula is no one's business except the owner's.

The real opposition, of course, arises from the apprehension that publishing the formula would hurt the “patent medicine” business. It is urged that the “patent medicine” manufacturers have spent large sums of money on advertising and creating a sale for their products, that, were their formula published, a host of imitators would arise who would claim to produce the same article, and who, having been spared the expense of advertising, could produce it at a lower price and thus drive the original manufacturers off the market. At first view, the argument appears quite reasonable, but on closer examination it is found to have some very weak features. In the first place, there are probably few druggists who do not consider themselves competent to imitate any “patent medicine” that is sold, even though its composition is supposed to be secret, at least, there are very, very few druggists indeed who do not think that they can produce something just as good, if not better. The cry against substitution, which we have heard for all these years, shows that secrecy has not protected against imitation.

It is most doubtful that the imitation would be any greater with the published formula than without it. It has never been demonstrated that the few “patent medicines” that do publish their formulas, such as castoria and the Ayer's preparations, are being imitated to any greater extent than the others. If the manufacturers are really serious in desiring protection against imitation, they could obtain this by patenting their formula — provided this is really original and meritorious — but there, perhaps, is the rub.

While it is not probable that the fears as to imitation need be taken very seriously, it is possible that publication of the formula would hurt the “patent medicine” business in quite another way. It would make it difficult, if not impossible, to advance the many extravagant claims of marvelous cures on which the “patent medicine” business is largely based. It would also undoubtedly greatly lessen the fictitious efficiency of the preparations in actual use. It might no longer be possible to remove or put on fat by the use of a little alum, washing soda or starch. The published formula would furnish a criterion of originality and efficiency, which many “patent medicines” could not withstand. Those that are neither original nor efficient would undoubtedly be hurt in their sale. It is doubtful, however, whether many outside of the “patent medicine” interests would shed tears over this danger. If a business is hurt by enforcing honesty, it is to the public interest that it should be hurt. In short, the publication of the formula would do but little harm, if any, unless there is the intention to defraud.

On the other hand, the published formula would be of some help to the honestly intentioned “patent medicine” manufacturers. In the first place, it would be the most efficient way of meeting the present feeling of the educated public against “patent medicines.” As is pointed out by the American Pharmaceutical Association commission, a given “patent medicine” may be of more or less, sometimes considerable, use in suitable cases. The fundamental objection to “patent medicines” as a class is that it is impossible to judge whether any of them are suitable to any patient, when their composition is not known. The patient often asks his physician whether it is safe for him to continue a “patent medicine” that he has used with apparent benefit, or to try one that has been recommended to him. In such cases, a physician would usually have no objection to humoring the wishes of the patient, provided he could be certain that no harm would result. With the composition secret, it is impossible for him to be certain of the harmlessness. He must, therefore, unqualifiedly prohibit the use.

The second argument in defense is that the publication would do no good to the buyer, because he would not understand the formula anyway. This entirely underestimates the intelligence of the public. Some do understand, and others seek advice. There are very few who would try to remove their fat with a little alum at an extravagant cost if they knew that it was alum. It is rather suggestive that several state laws require the publication of the formula of stock remedies. It can scarcely be contended that the farmer knows something about what “salts” is when giving it to a horse, but has never heard of it when he takes it himself!

The publication will also be of some service to the public in protecting it against a change in formula whenever the price of ingredients advances, or when other reasons prompt the manufacturer. I do not know how often such changes are made, but there is a widespread belief that they are not uncommon. The purchaser is certainly entitled to know when the thing that he buys under a given name is different from what he had formerly bought under the name.

A final argument, and to my mind the most important, is the protection of the public against drugs which may under some circumstances be perfectly harmless, but which may become very harmful under other conditions. One need only remember the dire results that would follow the application of calomel to the eye of a patient who is taking iodid — a frequent constituent of “patent medicines” — without the knowledge of his physician. Perhaps even more common are the instances of oversusceptibility to the effects of drugs. In these cases the patients and their physicians are generally aware that this or that drug should not be used. There are no statistics to show how much damage is done by the consumption of “patent medicines” whose constituents are quite harmless for the average individual, but against which certain people react abnormally, and which would be avoided if the consumer knew the constituents On the other hand, the patient may not know their susceptibility, and finally consult a physician concerning an unusual, obscure and intractable train of symptoms whose cause and cure would be clear the moment that the physician knew the drugs that had been taken

It may be argued, thirdly, that the formula is the property of the manufacturer, that the medicine is likewise his property, and that he can sell it under his own conditions If he chooses to keep the formula secret, and the purchaser does not like this, he need not purchase and no harm will be done If he does purchase, the transaction is strictly between him and the manufacturer, and the business of no one else The fallacy of this "individual liberty" argument has often been pointed out Logically, it would permit and legalize any sort of fraud It is now universally conceded that where the public has not the means of judging for itself, the state can and should step in to afford it protection A law requiring publication of the formula would still leave the formula the property of the manufacturer, and would not at all compel him to disclose it Only, if he wishes to keep the formula to himself, the state will also oblige him to keep the medicine to himself

The proposal to register the formula confidentially with a government body is a sort of middle ground that is supposed to guard the interests of the manufacturer, and protect the public against the grossest forms of fraud and the most marked dangers As a matter of fact, it can do neither satisfactorily It would not effectively protect the manufacturers, because the government commission — itself consisting of several individuals — would often need to call in outside advice to pass on the various claims, etc, made for each medicine, if it were to do its task at all conscientiously One can easily see what chances there would be for the leakage of information Once information had leaked, the much dreaded damage would have been done Who would assess and pay the damages to the manufacturer?

It would not effectively protect the consumer, because a composition that might be harmless for most individuals might be harmful for him, a manufacturer might make claims which the government body might hold to be justifiable in the majority of cases, but which would not be at all justifiable in individual cases The medicine might contain ingredients which are ordinarily not dangerous, but which become dangerous under certain conditions which the government body could scarcely foresee The cost of the medicine might be so extravagant that the individual consumer might consider it as fraudulent, the government body would have great difficulty in drawing a line

Let us not forget that a question is never settled until it is settled right, and that a settlement that is satisfactory to neither party is certainly *not* right

After the American Pharmaceutical Association commission has formulated its final rules, it will still be confronted by the problem of making these effective It may urge their enactment into laws, but until that can be accomplished, it must rely largely on the moral pressure that it can exert Perhaps the "patent medicine" manufacturers will themselves see the light and aid in the reform Or will they put themselves in the position of Belshazzar and his court and wait until sentence has been pronounced?

> They drank wine and praised the gods of gold, and of silver, of brass, of iron, of wood, and of stone
>
> In the same hour came forth fingers of a man's hand, and wrote over against the candlestick upon the plaister of the wall of the king's palace, and the king saw the part of the hand that wrote
>
> Then the king's countenance was changed, and his thoughts troubled him, so that the joints of his loins were loosed, and his knees smote one against another —Daniel, v, 4-6

CARBOHYDRATE INDIGESTION

WILDER TILESTON, M D
NEW HAVEN, CONN

Carbohydrate indigestion is not, strictly speaking, a disease, but a functional disturbance which may occur by itself, or as a complication of disease of the alimentary tract or of other parts of the body Scattered references to faulty digestion of carbohydrates are to be found, under the headings "Gastric Ulcer," "Meteorism," etc, in the current textbooks on diseases of the stomach and intestines, but the subject is, so far as I am aware, nowhere treated as a comprehensive whole Yet the condition is very common and responds readily to a proper regulation of the diet

The discussion will be limited to carbohydrate indigestion in adults, since the condition as it affects infants forms a subject by itself

There are distinct limits to the tolerance for carbohydrates, proteins and fats These limits vary widely in different persons, and in the same person at different times When the amount in the diet of one of these forms of food exceeds the limit of tolerance, then either disturbance of digestion, or of absorption, or both, is the result

Indigestion of various kinds is perhaps more often due to a diet unsuited to the individual than to any other cause The symptoms of carbohydrate indigestion are the result of fermentation, with the formation of various gases, carbon dioxid (CO_2) and methane, (CH_4) etc, and volatile fatty acids For fermentation to take place three factors are necessary (1) the presence of suitable micro-organisms, (2) a proper medium for them to work on, and (3) more or less stagnation of the contents of the stomach or intestine, in order that the organisms may have sufficient time for action A great variety of organisms may give rise to gaseous fermentation, among which the yeasts and various bacteria are the most important Kuhn and Strauss[1] have shown that hydrochloric acid does not inhibit the development of yeast cells Gaseous fermentation is found in the stomach, according to Riegel,[2] especially in cases of dilatation, with normal or increased amounts of hydrochloric acid, though it may occur in the absence of hydrochloric acid In the case of the intestines the colon is the chief seat of gas production, on account of the abundance of micro-organisms and the stagnation of the contents

The exact causes of carbohydrate indigestion remain obscure In the stomach, hyperacidity might be a factor by interfering with the action of the salivary diastatic ferment In the large intestine the presence of undigested or partially digested starch is probably the most important factor, for sugars are invariably absorbed higher up in the canal. The micro-organisms are probably always present and only await a suitable opportunity for their activity.

---

[1] Kuhn and Strauss Quoted by Riegel in Diseases of the Stomach, Nothnagel's Practice, Am Ed 1903 p 123

[2] Riegel Diseases of the Stomach, in Nothnagel's Practice, Am Ed p 403

The faulty digestion of starch in the intestine might be due to an insufficiency of the diastatic ferments, or, as A. Schmidt[3] suggests, to a defective digestion of the cellulose which forms the outer envelope of the starch cells, and must be removed to allow the digestive ferments access to the starch within.

SYMPTOMS

The symptoms of intestinal fermentation are chiefly those due to distention with gas. The patients in the milder cases complain only of a sense of fulness or discomfort coming on several hours after meals, and of flatulence. The higher degrees of tympanites are accompanied by colicky abdominal pain, which may be severe, and is relieved by the passage of gas. The seat of the pain varies according to the part of the intestine affected; it may be general, or located in the right iliac region, or the left side of the abdomen. Pain is more likely to occur if there are adhesions which are pulled on, as in the case of distention of the cecum with adhesions from chronic appendicitis. Sometimes the acid products of fermentation irritate the bowel to such an extent that diarrhea results, the so-called "fermentative dyspepsia," of Adolph Schmidt. The movements are then frequent, acid and foamy from the admixture of gas bubbles.

Gastric fermentation gives rise to distention of the stomach, which is relieved by belching. "Heart-burn" is another common symptom in this condition, and one that is relieved by diminishing the amount of carbohydrates in the food. Whether, however, the carbohydrate indigestion is secondary to the hyperacidity, or causes it by the irritating products of fermentation, remains an open question.

DIAGNOSIS

Since abdominal distention is the principal symptom of carbohydrate indigestion, it becomes necessary to consider all the causes of tympanites. These are four, namely, (1) increased gas production; (2) mechanical obstruction of the intestine; (3) the so-called paralytic ileus, or obstruction due to paralysis of the intestine, and (4) deficient absorption of gas from the intestines. Mechanical obstruction can only give rise to doubt in cases of chronic and partial obstruction; here a careful inquiry for previous inflammatory abdominal disease, and examination of the abdomen for tumor, visible peristalsis, and intestinal rigidity (*Darmsteifung*) will usually solve the question, though roentgenoscopy may be necessary before a final decision is reached. In paralytic ileus the symptoms are those of acute intestinal obstruction, usually associated with acute general peritonitis or following an abdominal operation. It is obvious that such a condition does not in the least resemble distention due to fermentation.

Tympanites from decreased absorption of gas is a rare condition, met chiefly in the aged, and presumably due to arteriosclerosis of the mesenteric vessels. The diagnosis can be made, with some reserve, in arteriosclerotic subjects with distention for which no other cause can be assigned.

After the exclusion of other sources of tympanites, that due to increased gas production remains. It is by far the commonest cause of distention. It may be the result of fermentation of either carbohydrates or proteins, but the carbohydrate fermentation is much the more frequent of the two. Therefore it will be allowable in a given case to limit the carbohydrates in the diet, and base the diagnosis on the results of treatment. A more certain opinion, however, can be reached by the examination of the feces. The reaction is perhaps the best single guide, an acid stool pointing to the carbohydrates, and alkalinity to the proteins, as the element at fault. The presence, under the microscope, of undigested starch granules, as shown by the iodin test, is additional evidence of carbohydrate indigestion, while a foul odor points with certainty to the putrefaction of proteins. The presence in the urine of large amounts of indican, or phenol, or both, also indicates increased protein decomposition. The fermentation test of Schmidt[4] is useful, though seldom indispensable. It consists in measuring, by means of a simple apparatus, the gas produced by a definite amount of feces when incubated for twenty-four hours in a thermostat, the reaction being taken before and after incubation. If the reaction becomes more acid, the fermentation involves the carbohydrates; if more alkaline, the proteins.

The fermentative diarrhea of Schmidt is easily recognized by the examination of the stools, which are mushy, acid, mixed with bubbles of gas, and contain undigested starch. Though the movements are increased in number, it is not, strictly speaking, a diarrhea, for the water content is not increased.

When belching is the principal symptom it is necessary to determine whether the gas is swallowed, or formed within the stomach. Cribbing, or the swallowing of air, is to be suspected when there is a history of a very large amount of gas brought up within a short space of time. On watching the patient, swallowing movements may be noted at frequent intervals, and the belching will be prevented by the wearing of a piece of cork between the teeth. If the gas is formed within the stomach, it may be due to simple carbohydrate indigestion or be secondary to obstruction of the pylorus or atonic dilatation of the stomach. The latter conditions may be distinguished by the use of the stomach pump, and of the Roentgen ray. Belching in a fat person is always suspicious of carbohydrate indigestion, for serious disease of the stomach almost always leads to loss of weight.

TREATMENT

The treatment of carbohydrate indigestion is mainly dietetic. It consists in a marked reduction of the total carbohydrate intake, with exclusion of certain articles which are known to undergo fermentation readily. Such are potato, sweet potato, cabbage, beans (except string beans), and chestnuts. The harmfulness of potato in this connection is possibly explained by the work of Lang,[5] who found, in the course of experiments with pancreatic diastase, that potato, though easily changed to achroodextrin, is very slow to undergo the further change into sugar. In obstinate cases, particularly in the fermentative diarrhea of Schmidt, it may be necessary to resort for a while to a strict protein-fat diet, consisting of eggs, meat, fish, bouillon, butter, and tea or coffee with milk or cream. According to Schmidt, a small amount of cane sugar and fruit jellies may be taken in addition to the above After a few days of such a diet, carbohydrates may be added cautiously, one at a time, sugar, cream of wheat, toast or zwieback, macaroni, and rice, in the order named Potato is best left out of the diet for a long time In cases without diarrhea, vegetables of low carbohydrate content, such as carrots, turnips, squash, egg-plant and string beans, are well tolerated from the first They should be sieved and served with butter

If obesity is present, a reduction in the total caloric value of the food should be combined with the limitation of carbohydrates The relief of indigestion is often a welcome by-product of an obesity cure

The results of the dietetic treatment of carbohydrate indigestion are most gratifying, dyspepsia of long standing disappearing in a few days In fact, if relief is not obtained, it is probable that the diagnosis is wrong and some other condition is present

The drug treatment of fermentation will accomplish little by itself When combined with regulation of the diet it sometimes seems to be of benefit, but as a rule it is superfluous The drugs most likely to give relief are the various salicylate preparations and beta-naphthol Belching can be facilitated by the administration of the ethereal oils, such as peppermint, or menthol in half-grain doses Diastatic preparations are occasionally of service

The following cases, all of which occurred in private practice, may serve to illustrate the foregoing statements

Case 1—M M, an unmarried woman, aged 67, was first seen Oct 1, 1914 Her past history was not remarkable except for a tendency to nervous prostration She had suffered from indigestion all her life, usually in attacks lasting from two to six weeks The chief symptom had been distention with gas, coming on two or three hours after eating, and causing a good deal of distress, sometimes enough to keep her awake at night When very uncomfortable she resorted to enemas to remove the gas The physical examination was negative except for gurgling on palpation over the intestines The feces were neutral in reaction, and were negative microscopically except for an excessive number of yeast spores The treatment consisted in a protein-fat diet, with a small amount of carbohydrate in the shape of sieved green peas and apple sauce A powder containing beta-naphthol, soda and bismuth was given after meals The result was prompt relief Three weeks later she reported that there had been very little gas though she had left off the medicine some time before Fruits once a day, nuts and ice-cream were then added to the diet At her next visit, November 6, she was feeling very well She was told she could eat rice, and after December 3, all vegetables except potato She reported by letter July 7, 1915 In the spring she had two short periods of indigestion lasting two days or less, since then she has been free from symptoms except an occasional feeling of abdominal discomfort

Case 2—Mrs D K, aged 43, was seen Jan 14, 1915 Her past history was negative For the past eleven years she had had frequent pains in the left iliac region associated with distention There was a constant dull pain there with acute exacerbations in which the pain radiated upward toward the left costal margin Examination showed a moderately obese woman, weighing 160 pounds, the viscera were negative except that the sigmoid was palpable The feces were slightly acid in reaction, and showed a few undigested starch granules On a diet low in carbohydrates she was soon relieved, and on February 3 reported that she had had pain only once in the last fortnight During the following week she had no pain On inquiry, June 26, 1915, she stated that she had been free from pain on a slightly restricted diet, except for a few occasions when she had taken more carbohydrate than usual

Case 3—Mrs R, aged 56, had been getting stouter for two years owing to lack of exercise following the death of her pet dog There was a good deal of heart-burn and gas in the stomach Under a simple antiobesity diet these symptoms promptly disappeared

Case 4—This patient was a very fat cook who complained of incessant belching The appetite was good but she was afraid to eat on account of the distress afterwards Complete relief followed restriction of the carbohydrates and of the total food intake

Case 5—C C, a college professor, aged 48, complained of distention from gas after meals, especially if he used his eyes directly after dinner Examination showed slight obesity, and the abdomen somewhat distended The stool was slightly acid, and contained many gas bubbles, and undigested starch granules The treatment consisted of a mild reduction cure with low carbohydrates A week later he reported that since changing his diet he had not been at all annoyed with indigestion Carbohydrates were gradually added to the diet without a return of the symptoms On inquiry six months later he said that he had remained well though on an ordinary diet

Case 6—This case illustrates the so-called fermentative dyspepsia of A Schmidt Mr S, aged 53, had been under treatment for the past few years for vague neurasthenic symptoms and for chronic prostatitis He complained of diarrhea of three months' duration The stools were two or three a day in number, and were mushy, not watery Examination showed a rather stout man, with nothing remarkable except the character of the stools, these were brown, soft, not formed, full of gas bubbles Microscopic examination showed numerous undigested starch granules He was put on a protein-fat diet consisting of eggs, meat and butter, with a small amount of carbohydrate in the shape of gluten-biscuit and tomatoes No drugs were prescribed A week later he reported considerable improvement, the bowels moving only once or twice daily, the stool partly formed He was told to add three slices of toast to his diet, and to take a teaspoonful of a diastatic ferment preparation after meals During the following week the movements dropped to one a day, and became formed and of normal appearance Carbohydrates were restored gradually to the diet list and no relapse took place

ACTIVE IMMUNIZATION WITH DIPHTHERIA TOXIN-ANTITOXIN

AND WITH TOXIN-ANTITOXIN COMBINED WITH DIPHTHERIA BACILLI — SECOND PAPER

LATE RESULTS *

WILLIAM H PARK, M D
AND
ABRAHAM ZINGHER, M D
NEW YORK

The property of diphtheria toxin-antitoxin mixtures to produce immunity in animals has been known for a number of years Successful results have been obtained in the immunization of horses (Park, 1902), goats, guinea-pigs, etc Theobald Smith suggested the immunization of children by this method, but no one undertook it until 1912, when von Behring made the attempt

In May, 1913, von Behring[1] reported the results obtained in human beings with mixtures of diphtheria

---

* Read before the New York Pathological Society, Oct 13 1915

* From the Research Laboratory and the Willard Parker Hospital New York City Department of Health

[1] Von Behring E Ueber ein neues Diphtherieschutzmittel, Deutsch med Wchnschr, 1913, xxxix, 873

toxin-antitoxin The combined substances were either neutral or slightly toxic to the guinea-pig, but the definite proportions of toxin and antitoxin were not stated The early reports of von Behring and his co-workers[2] were so favorable that we determined to make a similar attempt at the Willard Parker Hospital The scarlet fever pavilion offered us exceptional opportunities to determine the efficiency of this prophylactic treatment against diphtheria

Mixtures of diphtheria toxin and antitoxin were accordingly prepared in such proportions that they were either overneutralized (50 per cent of the L + dose of toxin to each unit of antitoxin), just neutral (from 66 to 70 per cent of the L + dose of toxin to each unit of antitoxin), or slightly toxic to the guinea-pig (from 80 to 90 per cent of the L + dose of toxin to each unit of antitoxin)

Several series of patients were injected with these mixtures during the past two and one half years Our first communication[3] in September 1914, gave the results which we had obtained within from four to six weeks after the injections of toxin-antitoxin From the available results at that time we concluded that the cases injected could be divided into two sharply differentiated groups

1 Those who had a natural antitoxic immunity produced a very decided increase in the amount of antitoxin after injections of toxin-antitoxin The response was very prompt and followed even after a single injection These individuals were, however, naturally immune even before the injections, and needed no further immunizing injections

2 Those who had no natural antitoxic immunity and were therefore probably susceptible to diphtheria gave entirely different results An early response (within from four to six weeks after the injections) to the active immunization was noted in only 25 to 30 per cent of the injected individuals The examination of the blood serum of these patients for antitoxin showed the presence of from one-tenth unit to 10 units per cubic centimeter Among those who did not definitely respond, however, a number gave a fainter Schick reaction[4] than the control test made before the injections of toxin-antitoxin This showed that at least a trace of antitoxin had developed in the cells and had accumulated in the blood This was not sufficient, however, to suppress the Schick reaction When we retested these individuals from six to eighteen months later, a large proportion now gave a negative Schick reaction and were thus found to have finally become immune

This late development of antitoxin is interesting in connection with observations which we had made with the Schick test in patients who had had diphtheria some weeks previously Among these we noted that fully two thirds still gave a positive reaction, thus indicating in these a failure to develop an antitoxic immunity within the period noted after one attack of the disease These figures correspond closely with the ones showing the early results of active immunization with toxin-antitoxin An interesting observation, however, was made in this connection when our chronic tube cases were tested who had had diphtheria eight months or more previously Nearly all gave a negative Schick reaction This may have been due to a late development of antitoxin or to the fact that the cells only slowly yielded up to the blood the antitoxin formed in small amount soon after the infection A few of these patients may have been subject to recurrent infections with the diphtheria bacillus There was, however, no proof of this In a group of four cases, for instance, in which a positive Schick reaction had been shown after an attack of laryngeal diphtheria, the gradual development of a permanent antitoxic immunity could finally be traced during the succeeding twelve months In another patient, who had developed an immunity soon after the disease, a persistent negative Schick reaction was obtained during the entire period of observation

These suggestive findings led to the conclusion that, while the immediate results of attempts at active immunization with toxin-antitoxin were disappointing, later ones obtained by retesting the immunized individuals without further injections might give a much better showing We therefore determined to follow up and retest, from four to eighteen months after discharge from the hospital, as many of the injected children as possible This tardy development of immunity in man is not unexpected, for it is a well-known fact that immunization of certain animals, like guinea-pigs, with diphtheria toxin alone or with the toxin-antitoxin mixture, is a slow process It almost seems that in some persons there is not only the absence of antitoxin but also some substance which destroys the first traces of antitoxin entering the lymph and blood so that some time elapses before an excess of antitoxin becomes apparent in the circulating blood The considerable success already noted of the tests of persons, some months after the toxin-antitoxin injections, led us to continue the work, and also to vary somewhat the methods employed with the hope of getting even better final results As is well known, diphtheria has shown during the past decade little decrease in morbidity, the mortality of the disease, however, has been greatly lowered by the early administration of antitoxin The problem, therefore, of an efficient method of active immunization in schools, asylums, hospitals and in the homes remains of great importance By means of the Schick test we can detect the susceptible individuals, and control in a simple and yet accurate way the results of the active immunization

The individuals who were retested with the Schick reaction to determine a late development of an antitoxic immunity can be divided into three groups The early results in Groups 1 and 2 may be summarized in Table 1

[4] Schick B Spezifische Therapie der Diphtherie Centralbl f Bacteriol 1 Abt. 1913 lvii Ref Beiheft, 16 Die Diphtherietoxin Hautreaktion des Menschen als Vorprobe der prophylaktischen Diphtherieheilseruminjection Munchen. med Wchnschr 1913 lx 2608. Park W H Zingher Abraham *and Serota Harry M* The Schick Reaction and Its Practical Applications Arch Pediat. 1914, xxxi 481 Park W H and Zingher Abraham Practical Applications Obtained from the Schick Reaction Proc. New York Path Soc October, 1914

In Group 1, sixty-eight patients were actively immunized No Schick reactions were made at the time, but for the sake of uniformity the results are stated in terms of positive or negative reactions The patients in this group were bled before and after immunization and the results determined by the examination of the serum for its antitoxin content

TABLE 1—EARLY RESULTS IN GROUPS 1 AND 2

Persons Injected		Reactions	About Four Weeks Later	Number Developing Diphtheria
Group 1	68	44 —	44 —	0
		24 +	6 —	0
			18 +	5
Group 2	90	90 +	20 —	0
				0
			70 + or ±	17

In this table, — = no reaction to toxin, and indicates presence of antitoxin, + = marked reaction to toxin, and indicates very little or no antitoxin, ± = moderate reaction to toxin, and indicates slight amount of antitoxin

Of the sixty-eight patients in Group 1, forty-four had natural antitoxin, and all gave a decided increase in antitoxin content after the injections, none developed diphtheria Of the remaining twenty-four patients who had no perceptible natural antitoxin, six gave rise to antitoxin production, while eighteen failed to respond Of the six no one, and of the eighteen five developed clinical diphtheria

Since the crucial value of the treatment lay in its efficiency to protect the susceptible individuals, we selected for immunization in Group 2 a larger series of cases which had no natural immunity, as shown by blood examination for antitoxin and by a positive Schick reaction Of the ninety injected patients, twenty responded to the injection of toxin-antitoxin with the production of sufficient antitoxin to protect against diphtheria, seventy failed to respond, though some gave a fainter Schick reaction than they had shown before the immunization Among the twenty, no cases of diphtheria developed, of the seventy who produced very little or no antitoxin, seventeen developed clinical diphtheria twelve days and more after the first injection

TABLE 2 —EARLY AND LATE SCHICK TESTS IN GROUP 2

Number Retested	Within Four Weeks	One to 1½ Years Later
16 +	5 —	5 —
	11 +	6 —
		4 ∓
		1 ±

In this and the following tables — indicates negative Schick reaction, ∓ faint, ± moderate, and + fully developed Schick reaction

From Group 2, sixteen cases were subsequently retested from one to one and one-half years after the injections of toxin-antitoxin (Table 2)

Five of the sixteen who had shown an early and decided production of antitoxin again gave a negative Schick reaction Of the eleven who had failed to respond at first to the immunizing injections, six now gave a negative, four a very faint and only one a positive Schick reaction

Group 3 consisted of 158 patients (Table 3) who had originally given a positive Schick reaction These patients were immunized with a mixture of toxin-antitoxin and a vaccine made of killed diphtheria bacilli Three or four subcutaneous injections were given at intervals of from three to four days, each injection consisting of 1 c c toxin-antitoxin (85 per cent L + dose of toxin to each unit of antitoxin), and 1,000,000,000 bacteria One c c of the mixture injected subcutaneously into a guinea-pig produced a slight local induration and paralysis in ten days

Local and general reactions were noted in about half of the injected individuals They were, as a rule, more frequent and more marked in the older children and in adults than in the young children These reactions are due in part to the slight excess of free toxin, and in part to the protein substance of the diphtheria bacilli, the more toxic mixtures will give, however, more severe reactions

Local reactions consisted of pain, redness, some induration and local tenderness at the site of injection The lymph glands in the axilla were not involved General reactions consisted of a temperature between 100 and 102 F and slight malaise The local signs appeared within twenty-four hours, lasted for another twenty-four hours, and then gradually disappeared The temperature continued, as a rule, only for one day, in some, for two days In no case have any serious effects appeared

TABLE 3—EARLY RESULTS IN GROUP 3 (158 CASES) WITH NO ANTITOXIN (+ SCHICK) BEFORE IMMUNIZATION

Number Injected	Within Four Weeks	Number Developing Diphtheria
158 +	56 —	0
	9 ∓	0
	83 ±	0
	10 +	4

Of the 158 injected patients, fifty-six, or 35 5 per cent, produced enough antitoxin within four weeks to give a negative, and 9, or 6 per cent, a very faint Schick reaction Of those who were partly or totally refractory, eighty-three, or 52 per cent, gave a moderately positive, and ten, or 6 5 per cent, a strongly positive Schick reaction Of the ten, four developed clinical diphtheria

To note any late development of immunity, we retested, from two to five months after the injections, fifty cases of this group (Table 4)

Ten of the patients who had given a definite early production of antitoxin continued to show a negative Schick reaction Of the thirty-six patients who had produced only a trace of antitoxin, sufficient only to inhibit slightly the Schick reaction, twenty-six now gave a negative, four a very faint and six a moderately positive reaction The remaining four who showed no antitoxin production at first, now gave a negative Schick reaction

TABLE 4—EARLY AND LATE SCHICK TESTS IN GROUP 3

Number Injected	Within Four Weeks	Two to Five Months Later
50 +	10 —	10 —
	36 ±	26 —
		4 ∓
		6 ±
	4 +	4 —

Grouping together the early and late successful results in this series of cases, we find that forty out of fifty susceptible individuals had developed an antitoxic immunity after the injections of toxin-antitoxin plus vaccine The remaining ten gave a reaction which was moderately positive in six and faintly positive in four cases These cases probably had also developed some bactericidal immunity from the bacilli injected

In addition to these, we also immunized with toxin-antitoxin a series of sixteen normal children (Group 4) who had given a positive Schick reaction These children were injected about a year ago, and retested with the Schick reaction four and eight months after the immunization (Table 5)

TABLE 5 —EARLY AND LATE SCHICK TESTS IN GROUP 4 (NORMAL CHILDREN)

Number Injected	Within Four Weeks	Four Months Later	Eight Months Later
16 +	4 —	4 —	4 —
	10 +	5 —	5 —
		5 +	4 —
			1 +
	2 ∓	2 —	2 —

Within four weeks after the injections, only four or 25 per cent, gave a negative Schick test Four and eight months later, these four still gave a negative reaction, thus indicating a probable lasting immunity Ten children who produced no antitoxin at first now showed the following interesting results At the end of four months, five gave a negative and five a positive Schick reaction At the end of eight months, nine showed a negative Schick reaction and only one was still positive Two of the sixteen children who had given a partial early response were found immune at the end of four and eight months

Sixteen months later, eight of the actively immunized children were retested Seven of those, who had become immune at the end of eight months, were found to be still protected, while the one who proved resistant again gave a positive Schick reaction

In the same institution, we also retested after sixteen months a number of normal children who had not been injected with toxin-antitoxin Table 6 gives the results of all the retests

The table shows that of fourteen negatively reacting children between the ages of 5 and 15 years, when retested after sixteen months, two gave a positive, but twelve still showed a negative reaction Of eighteen originally positive Schick cases, three were now negative while fifteen were still positive It is interesting to compare with these eighteen the group of eight children who had been actively immunized with toxin-antitoxin, their retests showed that a much larger proportion had become immune than could be accounted for by the time factor alone

TABLE 6—RESULTS OF ALL RETESTS

Date	Not Immunized		Immunized

	1 ±		

* Toxin-antitoxin.

From the retests in the naturally immune children in this series and in a larger one at present under observation by us, the rather important fact may be deduced that a great majority of children of school age, who show a negative Schick reaction, probably remain protected for years, and even for life *Such persistent* immunity, as shown with the test, could be successfully utilized in schoolchildren During an outbreak of diphtheria among children previously tested, it would be necessary to immunize with antitoxin only the susceptible children Class work could then continue without interruption

Our results in active immunization up to the present time have led us to the conclusion that, while the toxin-antitoxin injections cannot be depended on to prevent diphtheria in the presence of immediate danger of infection because of the slow development of immunity in a majority of the cases, yet the injection is of value in rendering a community or school population immune to the danger of infection from future exposure up to a period of possibly several years

The Research Laboratory will supply those connected with institutions, who are interested in the subject of active immunization against diphtheria, and are willing to furnish us a report of the cases, diphtheria toxin for the Schick test and a mixture of diphtheria *toxin-antitoxin* for immunization

The reports should include

1 The character of the Schick reaction before the injections and at the following intervals after the last injection three weeks, six weeks, three months, six months, one year and two years Pseudoreactions are to be carefully controlled

2 The number of *injections made* The dose recommended is 1 c c, injected three times at intervals of seven days The injections are made subcutaneously in the arm over the insertion of the deltoid The dose is the same for individuals from 1 year to adult life Infants below the age of 12 months receive 0 5 c c with each injection

3 The character of the local and general reactions, if any, after each injection

4 A description of the clinical cases of diphtheria which develop among the injected individuals during the course of immunization or afterward Culture reports for the Klebs-Loeffler bacillus, etc

5 Where possible, a quantitative estimation of the amount of antitoxin developed as a result of immunization

The following groups of individuals are recommended for active immunization (only positive Schick cases to be injected)

(*a*) Children in schools and orphan asylums

(*b*) Mothers and infants in lying-in places

(*c*) Physicians, nurses and ward workers in contagious disease hospitals

(*d*) Patients in general and contagious disease hospitals

CONCLUSIONS

1 Individuals who, before treatment, give a negative Schick reaction are immune probably for life and, therefore, it is not necessary to inject them, when exposed, either with antitoxin or toxin-antitoxin

2 Those who give a positive Schick reaction and are exposed to diphtheria and in immediate danger should receive either antitoxin alone or, if a longer protection is desired, both antitoxin and toxin-antitoxin

3 For the general prophylaxis against diphtheria in schools and communities, excluding immediate contacts, a mixture of toxin-antitoxin alone (from 85 to 90 per cent of the L + dose of toxin to each unit *of antitoxin) or toxin-antitoxin* plus vaccine of killed diphtheria bacilli is recommended The dose is 1 c c of toxin-antitoxin and 1,000,000,000 bacteria injected

subcutaneously and repeated three times at intervals of six or seven days Sufficient time has not as yet elapsed to judge the value of adding the injections of the bacilli to the toxin-antitoxin

4 The early and the late results of active immunization should be determined with the Schick test Early results are those obtained by the application of the test within four weeks, and late results from four months to two years after the immunizing injections

EFFECT OF MODERATE DOSES OF SOME OPIUM DERIVATIVES ON GASTRO-INTESTINAL TRACT OF MAN *

PRELIMINARY REPORT ON ROENTGEN STUDIES

HENRY K PANCOAST, M D
AND
ARTHUR H HOPKINS, M D
PHILADELPHIA

This work was undertaken as the result of the observations of one of us (Pancoast[1]) on the gastro-intestinal motility of a patient who had a hypodermic of morphin several hours before the Roentgen studies were made There was found not only an hour-glass constriction of the stomach, but also a striking retardation of the motility of the small intestine Control studies on this patient at a later date, and when freed from the influence of morphin, revealed no such abnormalities

The earliest investigations in which the Roentgen rays were utilized in the study of the action of opium and its derivatives on the gastro-intestinal tract were those in which animals, especially dogs and cats, were utilized These studies frequently revealed, not only a retention of the bismuth meal in the esophagus for a period of one-half hour, but also a retention, even for hours, in the fundus and not the pylorus of the stomach, owing to a constriction in the region of the pyloric antrum Intestinal motility was less influenced than gastric, and that of the large intestine less than the small (Magnus[2]) Later studies were made on the action of magnesium sulphate and colocynth with succeeding observations on the effect of morphin and opium administered shortly after the above-mentioned cathartics Magnesium sulphate caused a delay in gastric motility, but an acceleration of motility of the small intestine and colon, while morphin was found to check this activity only by means of further delaying the passage of the meal from the stomach to the bowel Colocynth produced first an increased gastric motility and then a delay The motility and secretion of the small intestine and the motility of the large was increased Morphin and opium checked the diarrhea by checking the activity in the small and large bowel, the tincture of opium being especially active in lessening the watery exudation (Padberg[3])

The work of Muller and Saxl,[4] in which the capacity of the stomach of dogs was estimated, not by the roentgenogram, but by a gastric fistula and the introduction of varying amounts of water, showed that the capacity was almost doubled in narcotized animals, morphin being especially effectual, then chloroform, then chloral hydrate and finally local anesthetics, as anesthesin Atropin produced a moderate relaxation, while epinephrin was ineffectual

More recently a few studies have been made of the influence of the opiates on the human gastro-intestinal tract as revealed by the roentgenogram Morphin was given by mouth and subcutaneously in varying doses In some instances, small doses increased peristalsis in the pyloric region, while moderate doses caused a constriction of the pyloric sphincter and occasionally an hour-glass constriction With large doses, the results were even more pronounced Very similar results were derived from the tincture of opium (van den Velden[5])

In nervous diseases of the "vagal neurosis" type, small doses were ineffectual Moderate doses, especially in young, nervous females, caused a prolongation of the emptying time of the stomach The emptying time of the small intestine was prolonged in all cases (Arnsperger[6]) Stierlin and Schapiro,[7] after similar studies, emphasize the influence of moderate doses of morphin on the retardation of the emptying time of the stomach in young people, in contrast to that of adults, the latter frequently being uninfluenced. In two cases of hypermotility, the emptying time was more rapid after morphin In over half of their series, the motility of the small intestine was retarded while the large intestine was but slightly influenced In chronic diarrheic enteritis, opium was found to retard the hypermotility of the small intestine

Quite recently, the roentgenogram has been used in the study of gastro-intestinal motility following the administration of various purgatives, the more important observations being those of Meyer-Betz and Gebhardt,[8] who used senna, jalap, calomel and salines, and Katsch,[9] who gave atropin, pilocarpin and epinephrin

We realize that our work so far is very incomplete, and this is offered only as a preliminary report on a subject we hope to follow and cover more conclusively during the next year It is based on careful examinations of twelve persons, including the one previously reported, to whom morphin was given, and one drug habitue who was permitted to resume the use of heroin for one day It has been possible to study these cases only when time would permit during the infrequent less busy intervals of full clinical and Roentgen laboratory hours Moreover, the cost of such research is a factor that has to be carefully considered Our studies have required 157 fluoroscopic examinations and the making of 170 roentgenograms

With the exception of the heroin case, a control series of examinations was made to check up each drug series at exactly the same intervals The corresponding plates were then studied side by side, together with the fluoroscopic notes We fully realize that

many cases would vary to a certain extent in two or even more control examinations, and also if more than one drug series were studied, and it is only by dealing with a large number of cases and selecting points of resemblance or widely different effects for tabulation that dependable data of any value can be obtained

RESULTS OF STUDY

An abstract of the results of study in each case follows

Case 1 — *Clinical Condition of Patient* — Aortic regurgitation

Medication—Digitalis and gentian, withdrawn during days of examination

Condition of Gastro-Intestinal Tract by Control Examination—Normal except slight colon stasis

Method of Administration of Morphin—Hypodermic injections, one quarter grain with first meal and one-quarter grain seven hours later

Effect on Stomach—Apparently none

Effect on Small Intestine—A slight but definite delay in motility as indicated by the relative position of the column in the lower ileum

Effect on the Large Bowel—(*a*) At the end of eight hours a definite but moderate relative slowing of the opaque column and probably more than could be accounted for by the lessened motility in the small bowel (*b*) At the end of twenty-one hours and later there was no difference from the control

Case 2—*Clinical Condition of Patient*—Gastric neurosis

Medication—None

Condition of Gastro-Intestinal Tract by Control Examination—Stomach negative, very slight delay in the terminal ileum due to incompetency, extreme colon stasis

Method of Administration of Morphin—Single dose hypodermic injection one-quarter grain with first meal (six hours before examination)

Effect on Stomach—Motility slightly increased throughout the time of examination, peristalsis slightly but definitely more vigorous, emptying time definitely shortened

Effect on the Small Intestine—At first a slight relative delay, indicated by the position of the column in the lower ileum Later as the second meal reached the intestine, there was a very decided delay in the jejunum

Effect on the Large Bowel—At the end of ten hours there was practically no difference from the control At the end of forty-five hours stasis was slightly accentuated

Case 3—*Clinical Condition of Patient*—Pyorrhea alveolaris and facial neuralgia

Medication—None

Condition of Gastro-Intestinal Tract by Control Examination—Stomach negative, slight ileal stasis moderate colonic stasis

Method of Administration of Morphin—Continued administration twenty-four hours hypodermic injections one-quarter grain with first meal one-quarter grain ten and one half hours later and one-quarter grain at the end of twenty-four hours

Effect on Stomach—Motility peristalsis and emptying time not appreciably affected

Effect on Small Intestine—The first dose caused no delay but on the other hand the column kept ahead of the control the second dose caused a slightly lessened motility in the upper small bowel which became less marked as the effect wore off

Effect on the Large Bowel—No delay from the first dose the column keeping ahead of the control, the repeated doses caused a decided delay over the control

Case 4—*Clinical Condition of Patient*—Infectious polyarthritis and oral sepsis

Medication—None

Condition of Gastro-Intestinal Tract by Control Examination—Negative except an extreme colonic stasis Inability to empty the large bowel after the control examination rendered it impossible to use this case further

Case 5—*Clinical Condition of Patient*—Possible pituitary neoplasm

Medication—Cannabis indica stopped during examination

Condition of Gastro-Intestinal Tract by Control Examination—Stomach showed varying motility, at times hypermotility but without hyperperistalsis Emptying time was delayed beyond six hours Otherwise negative

First Series *Method of Administration of Morphin*—Single hypodermic injection one quarter grain with meal

Effect on Stomach—Motility and peristalsis were not studied No residue in six hours whereas there was a decided one in the control examination

Effect on Small Intestine—None, unless a slight increase in motility

Effect on Large Bowel—Very slight relative delay in the head of the column

Second Series (the following day after enema) *Method of Administration of Morphin*—Hypodermic injections one-quarter grain one and one-half hours before meal and one-quarter grain two and one-half hours after meal

Effect on Stomach—The same hypermotility as during the control but peristalsis was markedly increased Emptying time prolonged considerably beyond control The hypermotility caused a decided overcrowding of the duodenum

Effect on Small Intestine—A decided delay in the duodenum with a large cap shadow which remained large after the stomach was about empty There was also delayed emptying of the third portion and a slight stasis throughout the small bowel

Effect on Large Bowel—Very slight relative delay over the control, more marked early when the drug was active

Case 6—*Clinical Condition of Patient*—Chronic pulmonary abscess

Medication—None

Condition of Gastro-Intestinal Tract by Control Examination—Negative except slight colonic stasis

Method of Administration of Morphin—Repeated doses by mouth, one-quarter grain one and three-quarters hours before meal one-sixth grain the same time after meal and one-sixth grain eight hours after meal for colonic effect.

Effect on Stomach—Motility A decided tendency to pyloric spasm especially early Peristalsis Marked hyperperistalsis, especially early and far more vigorous than during control One decided antiperistaltic wave Emptying time Delayed about two hours probably because of spasm

Effect on Small Intestine—Slight stasis in the upper portion and a decided relative ileal stasis

Effect on Large Bowel—A decided relative delay in the head of the column while the drug was active, but little if any delay later

Case 7—*Clinical Condition of Patient*—Heart case

Medication—Digitalis discontinued during examination

Condition of Gastro-Intestinal Tract by Control Examination—Stomach showed delay in emptying beyond eight hours Slight colonic stasis

Method of Administration of Morphin—Closely repeated doses by mouth one-quarter grain one and three-quarter hours before meal one-sixth grain one and one-quarter hours after and one-sixth grain three hours after

Effect on Stomach—Motility about the same as control, peristalsis more vigorous in the pyloric portion and continued so with deep segmenting waves, emptying time decidedly prolonged by the repeated doses although motility was ample after the first dose indicating spasm

Effect on Small Intestine—In upper portion a delay only after the third dose A slight delay as noted by the column in the lower ileum, for which the stomach was partly responsible

Effect on Large Bowel—Very little delay as the drug was given early

Case 8—This case deserves special mention because of its unusual interest from the clinical standpoint and because many of the unusual phenomena noted were similar to those observed in connection with the morphin case previously reported.[1]

Clinical Notes on Case.—Drug habitue, addicted to the use of heroin especially, and also cocain. Had been off heroin for two and one-half months. Was admitted because of the drug habit and his general condition resulting therefrom. No medication.

Condition of Gastro-Intestinal Tract by Control Examination.—No examination was made.

Method of Administration of Drug.—Six doses of heroin hydrochlorid, one-sixth grain, given the day before the examination by mouth every third hour. Following this a diarrhea started at night.

Notes Made at the Examination.—The first fluoroscopic examination was made directly after the administration of the opaque meal, without other food. The stomach showed a complete hour-glass constriction at about its middle portion and the appearance was similar to that observed in the previously reported morphin case.[1] This relaxed gradually but not completely, and as it relaxed, there was a tendency to hypermotility without any visible peristalsis (as observed also in the morphin case), and the entire duodenum became overfilled without the passage of any opaque material further. The noteworthy features were the early hour-glass constriction followed by gradual relaxation, hypermotility without peristalsis, and the distention and apparent atony of the duodenum.

Two hours later, the upper portion of the stomach still contained considerable opaque food, and it again showed a complete hour-glass constriction, with a small amount of contents in the region of the pylorus. The upper small intestine was well filled and showed lack of motility.

Four hours after the meal there was still a residue above the hour-glass constriction, and a small amount in the pyloric region. The upper small intestine showed even greater paresis. At the end of six and one-half hours the appearance was much the same, and at the end of eight hours there still remained some residue above the constriction, and the opaque column was progressing very slowly through the small intestine. The residue from the start of the examination had been almost entirely above the hour-glass constriction, and the lower half of the stomach seemed to empty readily and rapidly. There was no evidence of pyloric spasm as noted in so many of our morphin cases.

A sixth fluoroscopic examination, made twenty-four hours after the meal, showed almost all of the opaque material distributed throughout the coils of small intestine. The colon was distended with gas but contained very little bismuth.

Resume. *Effect on Stomach.*—Hour-glass constriction at middle, relaxing somewhat when the stomach was filled, and contracting again as it emptied. Motility. Marked hypermotility in the lower half, with retention in the upper half. Peristalsis not noticeable. Emptying time delayed over eight hours, but almost entirely in the upper pole.

Effect on the Small Intestine.—Primarily, overfilling of the duodenum and then a prolonged paresis of the entire small bowel, continued over twenty-four hours.

Effect on the Large Bowel.—This was not studied, as very little opaque material had reached it in twenty-four hours, and the patient's condition did not warrant further study.

Case 9.—*Clinical Condition of Patient.*—Early acromegaly.

Medication.—Liquid petrolatum, 30 c.c., twice daily, and mixture of sodium bromid, tincture of hyoscyamus and camphor three times a day. By mistake this was not discontinued during the control examination, and was therefore continued during the morphin studies.

Condition of Gastro-Intestinal Tract by Control Examination.—Negative.

Method of Administration of Morphin.—Closely repeated doses by mouth as in Case 7. One-quarter grain one and one-half hours before meal, one-sixth grain one and one-half hours after, and one-sixth grain three hours after meal.

Effect on Stomach.—Motility. The amount which passed through the pylorus was not commensurate with the peristalsis. There was an intermittent pyloric spasm which was very marked at times, wi[illegible] at other times the pylorus seemed to relax to a normal degre[illegible]. Peristalsis. Intermittent hyperperistalsis, which continue[illegible] throughout the examination.

Emptying time. No relative difference at first, but the repeated doses caused from two to three hours' delay.

Effect on Small Intestine.—Only a slight though definite effect at first, but a considerable relative delay through a large area after the repeated doses.

Effect on Large Bowel.—Delay at first evidently due to small intestine stasis. No delay at twenty-four hours (Patient taking oil.)

Case 10.—*Clinical Condition of Patient.*—Idiopathic epilepsy.

Medication.—None.

Condition of Gastro-Intestinal Tract by Control Examination.—Stomach negative, hypermotility, small intestine, slight colonic stasis.

Method of Administration of Morphin.—Closely repeated doses by mouth with concentration of effect earlier than preceding case, one-quarter grain four hours before meal, one-sixth grain one-half hour before, and one-sixth grain two hours after meal.

Effect on Stomach.—Motility. Decided hypermotility early, but this rapidly subsided until there was evidence of pyloric spasm later. Peristalsis apparently not affected until late, when it seemed to increase as pyloric spasm became manifest. Emptying time prolonged several hours as the later effect of pyloric spasm.

Effect on Small Intestine.—Motility still rather rapid, but lessened as compared to control. The duodenum was sluggish in propulsion.

Effect on Large Bowel.—Increase in colonic stasis, as indicated by position of head of column.

Case 11.—*Clinical Condition of Patient.*—Chronic bronchitis, infectious polyarthritis.

Medication.—None.

Condition of Gastro-Intestinal Tract by Control Examination.—Decided colonic stasis.

Method of Administration of Morphin.—Hypodermic injections given entirely before meal and carried to the physiologic action of contraction of the pupil, one-sixth grain ten hours before, one-sixth grain seven hours, one-sixth grain four hours, and one-sixth grain one hour before the meal. The only case in which any contraction of the pupil was noted.

Effect on Stomach.—Motility. Tendency toward intermittent pyloric spasm, which was rather overcome by increased peristalsis and gradually subsided as the effect of the drug wore off. Peristalsis irregularly violent at first but gradually subsided as the effect wore off. One antiperistaltic wave seen early. Emptying time not delayed, keeping pace fairly well with the control throughout.

Effect on Small Intestine.—No delay whatever at any time.

Effect on Large Bowel.—No delay whatever.

Case 12 (female).—*Clinical Condition of Patient.*—Meniere's disease.

Medication.—Sodium bromid and nux vomica, discontinued during examination.

Condition of Gastro-Intestinal Tract by Control Examination.—Nothing abnormal in connection with stomach, but patient vomited early in each series. Colon examination not made.

Method of Administration of Morphin.—Single dose hypodermic injection, one-quarter grain half an hour before meal.

Effect on Stomach.—Motility. Decided early and persistent intermittent pyloric spasm. Peristalsis greatly increased, deeper but not more frequent waves. Frequent antiperistalsis. Emptying time increased about two hours, owing to continued pyloric spasm.

Effect on Small Intestine.—Considerable relative delay throughout the examination of eight hours.

Effect on Large Bowel.—Not studied.

Case 13.—*Clinical Condition of Patient.*—Rheumatoid arthritis.

Medication.—None.

Condition of Gastro-Intestinal Tract by Control Examination.—Probably some perigastric adhesions not affecting function.

Method of Administration of Morphin.—Single dose hypodermic injection, one-quarter grain, forty-five minutes before meal.

Effect on Stomach—Motility No effect at first, but pyloric spasm became evident soon but gradually subsided as effect of drug wore off Peristalsis more vigorous than during control period, but not excessive. Later it became very inactive Emptying time delayed over four hours, owing to early spasm and later inactivity

Effect on Small Intestine—Decided stasis in upper small bowel including duodenum but without distention

Effect on Large Bowel—None

COMMENT

It should be borne in mind that the Roentgen examination is a method of studying only a single phase of drug effects on the gastro-intestinal tract It shows better than can be demonstrated by any other method how the various portions of the digestive canal act in the propulsion of opaque food contents when under drug influence as compared to their action during normal or control periods

We realize that even as a preliminary report our work is lacking in several important respects, and first of all in the small number of cases we have been able to study Secondly, after conclusive proof of certain definite effects due to morphin, we had expected to compare these results with those due to some of the other preparations of opium, but we found the effects of the former so unlike in different individuals that it was difficult to form a basis for comparisons Our experience has shown us that the only accurate way of making relative estimates would be to carry out a series of investigations with morphin and other preparations on the same cases Thirdly, we had hoped to add to our list of eleven morphin cases at least one showing the unusual idiosyncrasies to moderate doses of the drug manifest by obstinate vomiting, but none were available for the purpose In no one of the eleven of this series was repeated even the unusual phenomena observed in the case previously reported,[1] although the heroin case (Case 8) showed very similar effects

What little we have done has shown that there is an enormous amount of valuable work yet to be accomplished in connection with the study of drug action by the Roentgen examination There are innumerable therapeutic agents yet to be studied in this way, and the comparatively little work that has been done along this line needs further confirmation English literature is noticeably lacking in this field of Roentgen investigation

The most surprising result of our observations has been the lack of any degree of uniformity in the effects produced in different individuals This was as noticeable in connection with the stomach as it was in the intestinal tract While we have been able to duplicate the phenomena observed by other writers, we have found them to be far from uniform Van den Velden[5] states that small doses of morphin (0 5 cg) increased peristalsis in the pyloric region Our smallest dose was never less than three times this He found that moderate doses (1 cg) caused in addition a marked constriction in the region of the pyloric sphincter which we never observed, and could cause a complete hour-glass constriction, dividing the fundus from the pyloric region This was observed in none of the eleven cases in our series, many of which had much larger doses, but was seen in the case previously reported,[1] and in our heroin case Large doses (2 cg) increased the effects and caused opening of the cardia and vomiting, which was not observed by us

In two of the eleven cases the morphin in a one-quarter grain dose seemed to exert no noticeable effect whatever on the stomach or its motility The most striking effect was an increase in the emptying time, usually from two to four hours, and observed in seven of the cases In one (Case 11) it was not delayed although pyloric spasm was evident, and in another (Case 2) it was shortened There was decided evidence of pyloric spasm in seven cases, while motility was increased in two instances, in one of which, however, pyloric spasm was manifest late Peristalsis was increased in intensity, the waves being deeper and occasionally more rapid in all nine cases in which there was shown any appreciable effect from the morphin This proved, therefore, to be the most uniform finding Antiperistalsis was noted in three cases Peristalsis was usually increased only in the pyloric portion, but occasionally a hyperperistaltic wave was observed along the entire organ The increase was usually seen to be associated with pyloric spasm In some individuals small doses produced no appreciable effect, while in some the phenomena were as marked as were those observed in other cases following very much larger doses

Whether or not the increase in emptying time was due to hypersecretion which precipitated pyloric spasm, as has been mentioned by some writers, or whether it was even associated with a hypersecretion any greater than might be expected in prolonged retention, we are unable to state

Arnsperger,[6] van den Velden[5] and others call attention to the fact that because food remains longer than usual or normal in a stomach that is under the influence of morphin, the use of opium is undesirable in gastric conditions in which the emptying time is increased, as perigastritis, adhesions, ulcers, carcinoma or reflex pyloric spasm from outside causes No doubt this might be the case occasionally and the continued use would be so almost invariably, but we cannot see how any direct harm could result in these conditions in most instances from the occasional use of the drug when needed Moreover, how much additional effect morphin would have in prolonging the emptying time in such conditions, and especially those in which pyloric spasm is a cause of delay, as ulcer, is a field for further study On the other hand, because morphin delays the emptying time we would not consider its routine use indicated in conditions in which hypermotility is present, as achylia gastrica, and especially because of its effect on the small bowel

Practically all authors agree that morphin lessens motility in the small intestine Unlike the stomach, delayed motility in the small bowel seems to result from a lack of propulsion instead of spasm It may be manifest only as an apparent relative delay of the column in the lower ileum, which we have regarded as an index of a slightly lessened motility higher up along the tract In many of our cases, and especially in the one previously reported[1] and in the heroin case of this series, the lessening of the motility was so marked as to be noticeable throughout a large part of the small bowel This was most noticeable in the jejunum, but sometimes in the duodenum as well, or in other words, in the portions where the most rapid movement is normal Stierlin and Schapiro[7] raised the question of spasm of the ileocecal valve being a cause of delay there, but so far as we could note there was no unusual crowding of contents in the terminal ileum

Arnsperger[6] states that the small intestine showed slowing in all cases examined We found this to be fairly constant, having been observed in ten out of the eleven cases of the morphin series In the one exception, the case which received the largest dosage, and the only one in which contraction of the pupil was noted, no effect whatever was shown by the small bowel In one of the ten positive cases, which was examined twice, a single dose produced no appreciable effect, but at the second examination when the dose was doubled, there was a noticeable delay In another of the ten cases a hypermotility was lessened In nine of the ten cases showing delay, there was evidence of this in the upper portion of the bowel

Experience has shown that our method was not the ideal one for studying the effect on the large bowel, although our results were very much the same as those of others As a rule this part of the tract was studied at the end of the examination, after the active influence of the drug had subsided partially or entirely A more accurate method would be to administer the drug at about the time the cecum was filled and the terminal ileum nearly empty — from six to eight hours after the meal in the average case This was the procedure followed by Arnsperger[6] His results were very variable, however, with different doses and with different individuals given the same doses Stierlin and Schapiro[7] found that morphin had no effect of any consequence on the large bowel

In all of our cases the large bowel was studied in connection with the tract higher up Our conclusions were based mainly on the relative position of the head of the opaque column as compared to the control The colon was studied in ten cases, and a noticeable delay in the head of the column was observed in six, and no apparent effect in three, two of which received small early doses and the other case which received the largest dose of any In one of the ten, delay was doubtful

So far as we were able to judge, it made little difference whether the morphin was administered by mouth or subcutaneously The only accurate way to determine the relative effect of varying dosage would be to examine the same individuals repeatedly with increasing doses, as small or single doses in one individual may produce the same or a more marked effect than large or repeated doses in others Of the two sexes, females seemed to be more susceptible

CONCLUSIONS

The Roentgen examination is a valuable method of studying certain phases of drug effects on the gastro-intestinal tract, especially motility, and the knowledge it furnishes can be gained better by this method than by any other

Our observations were made in a series of eleven cases given morphin and one heroin habitue While we have been able to duplicate the phenomena observed by others, with one exception, there was a decided lack of uniformity in the effects produced in different individuals, in connection with both stomach and bowel

There is no distinct uniformity in connection with dosage Small doses in some may produce more marked effects than much larger doses in others Females appear to be more susceptible

In the stomach a rather high spasmodic hour-glass contraction is observed rarely, but we have not seen this near the pylorus as described by others In some instances the stomach may show no appreciable change from normal In most cases there is more or less pyloric spasm, increased peristalsis and a decided prolongation of the emptying time

In the small intestine, morphin causes decreased motility almost uniformly, apparently as a result of a lack of propulsion and not of spasm When marked, it is most noticeable in the upper small bowel

The effect on the large bowel is very variable and probably of little consequence

Oral administration produces practically the same effect as subcutaneous injections

THE ENDOWMENT OF CHILDHOOD FROM THE OBSTETRIC STANDPOINT *

JOHN F MORAN, M D
WASHINGTON, D C.

The present era in the practice of medicine, like the preceding periods, is one of transition, and the goal the conservation of health and the prolongation of life, is hampered by ignorance, mysticism, superstition and exploitation The beacons of scientific investigation, clinical observation and experience, however, are steadily revealing the mysteries of Nature, and are thereby enriching our knowledge in the alleviation, prevention and cure of disease Down through the ages each period has contributed more or less to this progress, and we are not unmindful of the rich heritage we enjoy in the possession of the accumulated knowledge and treasures of our predecessors which form the granite ground-work of the art and science of medicine

Each era has been distinguished for some epoch-making contribution Ours is particularly noted for the development of an aseptic technic which has revolutionized the practice of surgery and obstetrics We were present at the christening, if not the birth, of that science, bacteriology, which has placed preventive medicine and sanitation on a rational and enduring basis A half century ago the practice of surgery was mostly of an emergency character, caring for fractures, dislocations, gunshot wounds, etc, while today three fourths of the operations are elective and cover a wide field of application "No cavity is now too deep and no organ too important or vital to deter from direct interrogation By vision and tact, the gravity, density and magnitude of any, of every part, may be revealed to the sensorium and adjudicated by the unerring edict of positive knowledge "[1]

The more important advancements in obstetrics as the result of these recent developments are the awakening interest in prenatal care and the prevention of infant mortality, the practical abandonment of craniotomy on the living child, and the broadened indications for cesarean section

In my previous address[2] on "The Endowment of Motherhood," I made a plea for better obstetrics in general practice, and expressed the belief that the solution lies in more intensive training of the students in practical obstetrics and educating the public to the necessity of efficient care of woman in the most important epoch in her life

---

* President's address, read at the meeting of the Washington Obstetrical and Gynecological Society, Oct 8 1915

[1] Miller DeLaskie Tr Ninth Internat Med Cong ii, 302

[2] Moran, John F The Endowment of Motherhood, The Jour A M A, Jan 9, 1915, p 122

Of course, accrued benefit to the unborn child was implied in this advanced obstetric teaching and practice, but I wish now to direct attention more specifically to what has already been accomplished regarding its welfare and the prospective possibilities of the future

The importance of the subject does not arise from the frequency with which its problems are presented but from the grave emergencies created by them — emergencies which demand early recognition and prompt decision by the physician in that they involve the lives of the mother and child, as well as points of professional honor and conscience

The longer I practice obstetrics, the more deeply I am impressed with the difficulty which often presents itself of deciding when to interfere and what particular method of intervention to elect In no other field of medicine is a well-balanced judgment and skill more requisite for success, and not infrequently, even then, the result is fortuitous

"When it is realized that practically 38 per cent of the deaths under 1 year of age are due to causes mainly dependent upon the health and condition of the mother during pregnancy and confinement, that within the registration area of the United States of 154,373 infants under 1 year of age, who died in the year of 1910, 14,964, or nearly 10 per cent, lived less than one day, that 36,351, or practically 23 5 per cent, lived less than one week, it will be seen that the infant mortality problem cannot be solved adequately by any measures which leave out of their scope some attention to the care of the expectant mothers" Since the foregoing sentence was written, the mortality statistics for 1911, issued by the Bureau of the Census, show a more distressing situation than was revealed by the figures of 1910 With an increased death registration area (now covering 63 per cent of the total population), there was a decrease in deaths of children under 1 year to 149,322 as against 154,373 in 1910 But those who lived less than one day increased not only relatively but also absolutely, that is, from 14,946 in 1910 to 40,883, or 27 4 per cent, in 1911 These figures show that the efforts made to save babies through pure milk and more intelligent care have produced results, while lack of organized effort to reach prenatal conditions for a very considerable period or over any extended area has further emphasized its need[3]

TABLE 1—CAUSES OF DEATH FOLLOWING CONFINEMENT

Cause	No	Per Cent
Prematurity	250	40
Inanition	99	15 8

These figures of the death toll of early infancy are appalling, and show that besides the unavoidable mortality incident to childbirth, many infants are born hopelessly handicapped for life's struggle, while many more perish through ignorance and neglect

The illuminating papers of Williams,[4] and Holt and Babbitt,[5] *on institutional infant mortality incident to childbirth and the two weeks following, show on careful analysis of 10,000 consecutive cases by each reporter how a very large percentage of the mortality could have been averted by intelligent supervision of pregnancy and competent care during labor*

TABLE 2—STILLBIRTHS (INCLUDING ABORTIONS)

Cause	No	Per Cent
Unknown	342	47 4
Congenital syphilis	84	11 7
Accidents of labor (dificult and prolonged 50 prolapsed cord 64 cord around neck, 5, knotted cord, 4)	123	17 1

Accidents (violence)	28	3 9
Monsters	6	8
Placenta praevia	30	4 1
Accidental hemorrhage	23	3 2
Miscellaneous	11	1 5

In this connection I wish to invite attention to a summary of a review of 10,533 confinements which occurred in the obstetric service of Columbia Hospital from July 1, 1876, to June 30, 1915 They were divided as follows stillbirths (including abortions), 716, living births, 9,817

The hospital is open to the profession All classes are received More than 60 per cent are admitted in labor, and over 70 per cent of the confined are colored The free patients are discharged on the eighteenth day, though in case of illness the time is extended to meet the requirements

It will be observed from the tables that the "unknown" forms the largest contingent of fetal deaths — nearly 50 per cent of the stillbirths and 24 per cent of the total *infant-mortality* This is because diagnosis was usually based on clinical data and often incomplete history, and frequently because a satisfactory explanation was wanting Routine Wassermann, other laboratory tests and necropsies would surely have proved many of this group to have been due to syphilis Bearing on this point, the following data furnished me by Mr Peter, the pharmacist, is of much

TABLE 3—GENERAL MORTALITY

Cause	No	Per Cent.
Unknown	342	24
Prematurity	250	18 5
Accidents of labor	157	11 7

[5] Holt L. Emmett, and Babbitt nal Mortality of the New Born The Journal A. M 287

significance Of 171 Wassermanns done in the past four years in the obstetric department, 113 were positive, and out of this number thirty-five, or 30+ per cent, were stillbirths Out of the fifty-eight negative reactions there was only one stillbirth It would probably be a safe estimate to say that at least 40 per cent of the unknown stillbirths was caused by syphilis

Prematurity, syphilis, inanition, atelectasis and toxemia constitute nearly 70 per cent of the total mortality, and are independent of labor. These factors influence pregnancy disastrously, and yet are largely preventable and amenable to well-directed treatment

The causes intimately connected with intrapartum mortality are malpresentation, forceps operations (asphyxia and intercranial hemorrhage), placenta praevia, ablatio placentae, rupture of the uterus, eclampsia, tetanic uterine contractions, etc, and were responsible for 18 per cent of the fetal deaths

It is difficult to estimate the probable percentage of this group that might have been saved, because many operators officiated and naturally the judgment and skill varied accordingly I know, however, from personal experience and observation, extending over a number of years, as intern and member of the visiting staff, that I and others were responsible for some of the mortality because of errors of judgment and execution

Pneumonia and enteritis were the most frequent mortality factors after confinement, and with the miscellaneous and accident groups made up 9 per cent of the total, while hemorrhages of the new-born and malformations and monsters yielded 3 per cent

This summary emphasizes the indubitable fact that there is a needless sacrifice of infants because of the neglect of prenatal care, and that early recognition of abnormal conditions and timely intervention would have averted many of the intrapartum disasters

The public should be taught that the risks attending parturition can be, for the most part, avoided by intelligent oversight of the parturient, by preparedness for rendering aid when needed no less than by masterly inactivity when normal

Much good is being accomplished by the various organizations engaged in the welfare of motherhood and childhood, by stimulating general interest in the cause and securing lay and professional cooperation, but if this much to be desired beneficence is to become nation-wide, the checking and follow up system can be satisfactorily done only under state subsidy and control

For some inscrutable reason, the life of the child has been held to be of unequal value compared with that of the mother, and in complicated childbirth, when both lives are in jeopardy, the child is to be sacrificed This is contrary to natural law, according to which all lives are equal, and furthermore, science has shown that this dictum is untenable in that there is no conflict between the life of the mother and the life of the child, and the direct sacrifice of either in the interest of the other can be defended, if at all, only on the ground of expediency and not on the claim of justifiability

Expediency is a subterfuge used to subordinate right and justice to might and convenience, whether it be in the stifling of a human life in its inception by that heinous crime of convenience, criminal abortion, or the deliberate taking of a life in the fulness of its development and when ready for external existence by a destructive operation

The passing of craniotomy on the living child is one of the greatest triumphs of modern obstetrics — a veritable turning of defeat into victory Practiced almost from the dawn of civilization, down through the centuries, this mutilating operation is happily being supplanted by humane methods of intervention that have for their purpose the saving of both lives

In this connection, I quote from the recent interesting paper of Dr Wall[6]

> It cannot be charged against us, as it was in the earlier days of medicine, that the interests of the child are entirely subservient to those of the mother The abandonment of craniotomy on the living child was an acknowledgment of infantile rights, which, thanks to modern advancement in medical science, have attained a station hitherto unknown, so that the mortality of the child is mentioned in the same breath with that of the mother in almost all obstetrical conditions and procedures
>
> I am of opinion that there is still room for improvement in judging the rights of the unborn child, and there are certainly enormous opportunities for advancement in the consideration and attention bestowed on the little individual after birth

It is to the honor of this society, dedicated to the cause of motherhood and childhood, that its first anniversary (1883) was made memorable in the defense of the rights of the unborn child The president, Dr Busey, in a trenchant and forcible address, challenged craniotomy on the living child as being unethical and unscientific, and, in the light of medical progress, should be abandoned in favor of cesarean section and other conservative measures

Until less than twenty-five years ago, cesarean section was rarely performed save for contracted pelvis, obstruction of the birth canal by tumors and in the case of sudden death of the mother, while today it embraces in its broadened scope not only deformities of the pelvis but also some cases of placenta praevia, eclampsia, disproportion between the size of the child and the pelvis, heart disease, ventrifixation, stenosis of the cervix and vagina, edema of the vulva and accidental hemorrhage, and a member of this society, Dr Bowen, has recently advocated it for certain breech cases, particularly, in aged primiparas after a test labor, even though the pelvic measurements are normal

I am in accord with this recommendation, for the usual methods of practice in this class of cases are attended with an infant mortality of from 10 to 20 per cent In discussing the case reported by Dr Bowen, I said

> Under the conditions mentioned with the patient showing signs of fatigue, evidenced by increased pulse rate, uterine inertia, etc, cesarean section was not only justifiable but a rational method of procedure, even though the pelvic measurements be normal If the bag of waters were intact and condition of mother and child favorable, some would advocate further trial aided with sedatives Instead of putting forth "the desire for a live child," I would make it stronger by substituting "the inherent moral and legal right of the child to be born alive" I had two somewhat similar cases recently in consultation, in one of which I resorted to slow extraction, against the better judgment of the attending physician, who suggested the advisability of cesarean section, lost the baby and got severe perineal laceration and colon infection In the other case, classical cesarean section was done with happy results to mother and child

---

[6] Wall The Status of the Child in Obstetric Practice, read before the Washington Obstetrical and Gynecological Society

In the complications that confront the obstetrician, there is none that is fraught with more danger or attended with greater anxiety than placenta praevia, save perhaps eclampsia Its sudden manifestation, often alarming hemorrhage and consequent anemia, shock and possible infection present a formidable array of difficulties that even in the hands of the most skilled has been attended with a high maternal mortality It is true that in recent years, with more definite method of treatment and advances of antisepsis and sepsis, the maternal death rate has been greatly lessened, but the extraordinarily high proportion of infants lost remains unchanged

If we analyze the statistics, we cannot fail to recognize that it is the lateral and marginal varieties that have contributed largely to this improved showing by directly sacrificing the life of the child by using it as a plug to control the hemorrhage In central implantation, modern methods have not materially affected the death rate It was quite natural, then, that other measures would be evolved with the hope of reducing the frightful infant mortality, while still not increasing, if not improving the chances of the mother Hence for more than two decades, from time to time, the justifiability of cesarean section in certain cases of placenta praevia, in the interest of the child as well as the mother, has claimed the attention of the profession Some have recommended it on theoretical grounds, with the conclusion that it is not only justifiable, but also indicated in central implantation of the placenta On the other hand, there are those who are equally positive in their belief that cesarean section has no legitimate field in placenta praevia, contending that the mother's life is of paramount importance and further, that many of the infants will of necessity be born prematurely and likely to succumb at birth The physician has no moral right to decide between the value of two lives, nor is he in conscience capable of determining whether the child will survive or not Both are his patients, entitled to his best skill and he is in honor bound not to deliberately sacrifice the life of one to save the other

The induction of premature labor, though offering little danger to the mother, is opposed on the ground of fetal mortality Besides, it is not an easy matter to determine the time for intervention, and the widest experience and most painstaking study and keenest mechanical sense are requisite for successful issue of this operation

Expediency rather than fitness is often the determining factor in choosing the method of intervention in obstetric practice The physician without surgical bent or training relies on such measures which, while usually safeguarding the mother's welfare, are often inimical to the interests of the child How often do we see cases of delivery by forceps or version in which the child is sacrificed at birth or dies within a few days afterward of cranial hemorrhage? It is with the borderline cases that we have so much difficulty, and they require the most exacting care in deciding how best to act in the interests of both lives The great mistake that many make is to apply forceps in cephalic presentations regardless of position and whether the head is engaged or not The cardinal rule is that forceps should never be applied to a head that has failed to enter the brim of the pelvis, for in a very large percentage of cases disaster will be almost sure to follow

I do not wish to be understood as in any way underestimating the value of forceps, version and the induction of premature labor, as they have their field of usefulness, nor am I unmindful of the fact that in the majority of cases the children would deliver themselves unaided, but what I do advocate is that more attention be given to the patient during pregnancy and that at the appropriate time a careful and thorough examination be made so as to be prepared to intervene at the proper time in the interest of both mother and child

During the past year considerable attention has been given to *Dammerschlaf* or "twilight sleep" in the medical and lay press The Freiburg method was tried out in this country nearly a decade ago and practically discarded Through the restatement of the method by one of the proponents, reiterating its claims for producing amnesia in labor, and the prompt exploitation of the address in a lay magazine article, the interest in the treatment has been reawakened, and the method is again being given a trial in several hospitals and by others It matters little whether the lay propaganda is due to the alluring euphony of "twilight" or to commercial cupidity, when compared with the duty of the profession to settle definitely whether the method possesses the value claimed for it This the searchlight of experience will determine, and the profession will before long be able to decide if it is to fill a much desired want in obstetric practice or share the fate of spinal analgesia

With a view of learning of the status of *Dammerschlaf* in Germany and elsewhere in Europe, I wrote to Professor von Heft, director of the Frauenspital, Basel, Switzerland He replied as follows

> I do not employ *Dammerschlaf* (twilight sleep) because it requires constant supervision also because it excites a number of the patients and in my judgment the infants are likewise endangered Years ago I made experiments which did not satisfy me The results are given by von Dietschy whose article I send you In a large maternity like this where the lying-in women cannot be isolated, the treatment is according to Kronig, contraindicated So far as I can see, *Dammerschlaf* is little used in Switzerland If used at all it is by physicians who have private clinics, hence 'painless labor' is to them a valuable advertisement In Germany also one does not enthuse greatly, and I believe the majority of my colleagues decline this method for example Fehling In isolated cases, quite naturally, it is of service

This criticism, from the knowledge I have gathered from the current literature, is very fair That scopolamin will produce amnesia is conceded, but its utility and freedom from danger are not generally accepted Reports of its indications and limitations are accumulating, and the almost universal discordant note is that it is not without danger to the child Dr Mundell has kindly placed at my disposal the replies of eight of the leading obstetricians in this country to whom he wrote asking advice regarding the use of the Freiburg treatment Those who favor its use restrict it to the first stage, and all but one emphasized its danger to the infant

There has been much undeserved criticism of those investigators who insist that the treatment should be given only by an expert The fact that it should be administered only by one who has had experience and that it is not feasible in general practice will, if for no other reason, operate against its general adoption

The field of obstetric practice has rarely been invaded by the quack, the work being too arduous and unremunerative, but the physicians who for mercenary considerations are imposing on the credulity of their insistent patients for the Freiburg treatment, by giving them "near" twilight sleep, are courting charlatanry

Obstetrics appears, as it passes before the mental vision, like a panorama of light and shade Supposed discoveries in the science and improvements in the art illuminate the scene, till the crucial light of experience casts a shadow of disappointment over the factitious light. We seek the truth Physicians know too well that the search is surrounded with difficulties, for we advance along the asymptote of the hyperbola, though we have not attained the absolute, we are approaching the object of our quest[1]

There are still many problems in obstetrics to be solved, including a remedy that will produce amnesia in labor or preferably eutocia, at will — *tuto, cito, jucunde,* safely, quickly, pleasantly Meanwhile let us continue to mitigate the pangs of labor with the measures which in succoring the mother do not jeopardize the life of her child

The keynote to decreasing the appalling infant mortality is good obstetrics, and the watchword is efficiency — efficiency in prenatal care — so that at the time of birth, mother and child shall be in the best possible condition, and efficiency in the conduct of labor, whether it be in the rôle of "watchful waiting" or masterly activity, in order that the child shall be assured its inalienable right to be born alive and healthy, and the mother safeguarded to a successful and happy fruition of her noblest mission in life — maternity

WHERE CHIROPRACTORS ARE MADE

THOMAS F DUHIGG, M D

DES MOINES, IOWA

As the season for legislation approaches, I feel that the information I have concerning chiropractors should be put at the disposal of those interested in guarding the public health and maintaining respectable educational standards The chiropractor's machine-made bills will be introduced into the legislature of every state where they have not received recognition

Iowa schools of chiropractic probably graduate more than the schools of any other three states Davenport is called the home of this sect, but Iowa does not recognize chiropractors, and they are liable to a fine of $300 if they practice here Obviously they swarm to other states, in some of which they are permitted by law to practice, and in others they are merely tolerated It strikes us as peculiar that other states, some with high educational standards, should take large consignments of our "graduate" chiropractors who have graduated from schools which require no preliminary qualifications and which have no libraries or hospitals — graduates of schools without any standing, inspected by no one, regulated by no one and conforming only to their own low estimate, which refers entirely to financial and not at all to scientific standards

After reading the reports of the inspector of the state of Pennsylvania, I believe the forty-seven other states will exclude the graduates of the Iowa schools of chiropractic the same as Pennsylvania has done This report is remarkable in that it was made by one outside Iowa and in the interest of the health of the people of a far distant state It is a testimonial to the care and judgment exercised by the officials of the great commonwealth of Pennsylvania in safeguarding the lives and health of those they are sworn to protect Likewise it is an indictment of the officials in all those states which have accepted these graduates without first having made a careful inspection and ascertained the extreme wretchedness of the physical equipment of the schools and the mental equipment of their graduates

The accompanying tabulation gives the reports on the three schools of chiropractic at Davenport, Iowa, made by the inspector of the Pennsylvania Bureau of Medical Education and Licensure

CHIROPRACTIC COLLEGES OF IOWA

A TABULATION FROM REPORTS OF THE INSPECTOR OF THE PENNSYLVANIA BUREAU OF MEDICAL EDUCATION AND LICENSURE

	Davenport College	Universal College	Palmer School
Buildings	One, an old church	One fair size	Four (crowded)
Access to hospitals	None	None	None
Dispensary facilities	Saw no evidence of	Ample *	
Admission requirements	None	Common school	Common school
Anatomy, dissecting	Not taught	Dissect a few dogs	Only dogs dissected
Histology	No equipment	Didactic only	Very incomplete
Embryology	Not taught	Not taught	Not taught

Obstetric manikin	Part of one	Yes	Yes
Maternity work	Not taught	Not taught	Lectures only
Charts	A few	Large supply	Large supply
Models	None seen	Yes	Yes

* This subject is taught only from the chiropractic standpoint, as it is related to certain spinal "lesions"

Regarding the individual colleges the inspector made the following statements

Davenport College of Chiropractic—"Their alleged 'chemical laboratory' consisted of a table about 18 inches square, on which were six dusty bottles and three dirty test tubes There were no records of work done by the students or of attendance at lectures or clinics"

Universal Chiropractic College—"They are not in any way equipped to give the character of instruction that would make their graduates safe advisers to the sick"

Palmer School of Chiropractic—'They pretend to give a course in obstetrics with no practical experience A person who assumed to practice on information gained from this course alone would be dangerously incompetent

Some of their professors are exceedingly ignorant The 'professor' of chemistry alleged he taught the Widal test' chemically but chemicals for even ordinary tests were not in evidence *those in evidence* showed no marks of use, most of the bottles being still sealed

The institution is not physically equipped to turn out safe graduates"

A letter *from* Dr *J* M Baldy *president* of the Pennsylvania Bureau of Medical Education and Licensure to whom the manuscript of this article was submitted states as follows

'The data quoted from our inspection is correct I have gone over it myself and have submitted it to the inspector"

It is sufficient to say that the three schools are uniform on the following points None has a library, a hospital, a laboratory that is worthy of the name, postmortems or capable teachers Add to this farce students without preliminary education beyond the mere ability to read and write and who "graduated" after a course of only one year in one of these "colleges," and we have an individual who is hopelessly handicapped for life, one who cannot in any sense be considered a safe adviser of the sick

These reports set forth everything with painful exactness and embarrassing detail Any patriotic legislator will be justly incensed at the thought of taking the intellectual refuse from these schools who are not permitted to practice in Iowa, to be used in his own state as the guardians of life and health They should not be given legal recognition to practice in any state If they are permitted to practice, it should be only after they have obtained the same professional and preliminary training that is required of physicians, which in Iowa is a high school education and two years of collegiate work plus four years of professional training in a medical school that maintains a standard satisfactory to the licensing board

---

Inconsistency of the Antivivisectionist.—Of course there are all sorts of men among physicians and surgeons as in all other professions Abuses and outrages do occur, no doubt There have been wicked doctors who have abused their trust, and there have been clergymen with whom the virtue of a young lady boarder was not safe, but we need not say for this reason that all surgeons are arch torturers and that all preachers are arch-lechers Just as you do not need to pass a special law against adultery by ministers of the gospel, but that if you did so you would put an imputation on the character of a large body of earnest, sincere and unselfish men, so you should not pass laws which would put on men in biological research the imputation of bad faith and cruelty Make the general laws against cruelty to animals as strict and far-reaching as may seem necessary for the good of the human race, but do not single out the men who are devoting their lives to the search after that knowledge *which is for* the best good of the race, and make them the special objects of unnecessary restrictive limitations If experiments on animals must be prohibited let the same law prohibit castration of animals and the dehorning of cattle If the English law requiring all operations by a scientific man to be done under anesthesia be adopted then require that operations on the farm be performed in the same way —Maxwell, *Science*

RECTAL AS A SUBSTITUTE FOR VAGINAL EXAMINATIONS IN LABOR

RUDOLPH WIESER HOLMES, M D
Associate Professor of Obstetrics and Gynecology, Rush Medical College
CHICAGO

In spite of the most rigorous regard to the details of asepsis in the preparation of the patient, of the attendant's hands, and of the supplies which may directly or indirectly approach the two, the dangers of puerperal infection have not been reduced to that negligible degree which our profession should attain Since the days of Carl Braun, various authorities have recognized the dangers accompanying vaginal examinations, have strenuously demanded the diminution of their number, and have sought means whereby such curtailment might be possible All modern authorities are agreed that vaginal examinations, no matter with what conscientious regard to aseptic technic they are conducted, carry with them their risk of sepsis Today it is generally recognized that abdominal palpation, aided by a proper interpretation of clinical evidences, offers as much, if not more, certitude as to the condition of the woman and progress of labor than do vaginal examinations alone The elimination of the necessity of entering the vagina, or at least reducing the frequency to the point at which imperative exigency demands it, will be a distinct obstetric advance In this paper, I would show that rectal examination fulfils this purpose, and that rectal will secure as much definite information, in most particulars, as do vaginal examinations, and without the risks of infection which inevitably accompany the latter

When ventral fixation was a popular procedure, I found it expedient, in a number of women in labor, to endeavor to reach the cervix by rectal palpation This was merely applying a method resorted to in gynecologic cases when, as in virgins, it was impracticable or impossible to use the vaginal route However, this did not suggest the full value of the method in the conduct of labor Two or three years ago the broader application was grasped from a source not determined At first, used in an incidental manner, then as a routine, an experience matured which has convinced me that it was an invaluable method of investigation Now, I am certain that rectal examination, supplementing abdominal palpation, should largely supersede vaginal touch in the conduct of *normal labor*, and in certain pathologic cases to be hereinafter mentioned, the latter route should be reserved solely for those cases in which the findings are inconclusive, or as a preliminary to operative work through the parturient canal

Rectal, as a substitute for vaginal examination, was suggested by Kroenig,[1] Nov 20, 1893, in a paper read before the Obstetric Society of Leipzig The method was introduced in his clinic early in August, 1893 The midwives quickly developed a facility in the procedure, so that in the three months covered by his report, 90 per cent of all labors were conducted by rectal examination alone He deduced the following conclusions

1 Midwives could palpate the spines of the ischia, determine the movability of the coccyx, and estimate the degree of resistance of the perineum

2 They could determine whether the presenting part were in the pelvis or not

---

[1] Kroenig Zentralbl f Gynak. March 10 1894

3 They could recognize the sutures of the forelying head

4 They could determine the relationship of the crown of the head to the bisischiatic line

5 They could determine the dilatation of the os definitely in multiparas In primiparas, errors were apt to occur, when effacement was completed

6 Generally the fontanels were not to be differentiated

7 The promontory was palpable only when a high grade of pelvic contraction existed

Independently of Kroenig, Emil Ries,[2] now of Chicago, began an investigation of the possibilities of rectal examination, in January 1894, in the Strassburg clinic, and published his results a few weeks after Kroenig The possibilities of the method were largely determined by Kroenig through the work of the midwives Therefore, we have conclusive evidence of its worth as a means for general application Ries' deductions were fixed largely by the results obtained by his own personal experience As a consequence, his findings are more valuable, more comprehensive and more utilitarian for the working needs of the medical attendant He corroborates the teachings of Kroenig, but has determined the far wider range of its applicability than Kroenig concedes for the method Ries has presented the only extensive monograph on the subject, an opinion based on a very cursory review of the literature Only one American textbook on obstetrics mentions the utility of rectal examinations, in a paragraph which includes four or five lines F Menge[3] gives an adequate interpretation of the application of rectal examination He says, "If one combines it [abdominal palpation] with rectal examination, then after a little practice, one is able to judge in every single case all diagnostic and prognostic details with certainty, even if the case comes after the onset of labor " He further recommends that a single vaginal touch is to be undertaken only when the combined external palpation and rectal examination is not clear in every particular

That the logical position of rectal examination may be properly presented, I shall give the usual factors which must be determined by routine vaginal exploration These are taught in most recent textbooks, and are the factors which essentially are to be determined by the new method of investigation At this point I can but mention the necessity of a definite procedure with every woman who presents her case to the obstetric attendant The physician should make it an invariable rule to study carefully every woman by repeated abdominal and pelvic examination during the months of pregnancy, in order that he may be conversant with her normality or abnormality, so he may properly and intelligently supervise the labor

FACTORS TO BE DETERMINED

Vaginal examinations in pregnancy, as we have learned by precept and example, should comprehend the determination of the following facts

1 The pelvic size, its normality or abnormality

2 Soft parts their normality or abnormality (*a*) the perineum, (*b*) the vagina, (*c*) the cervix and os, (*d*) recognition of tumors in or about the lower segment — placenta praevia, etc , (*e*) the rectum

3 The fetus presentation and position, the cephalopelvic adaptability

Further, in labor additional data must be determined

4 The fetus (*a*) revisional diagnosis of presentation and position, which must be made because many of the deviations from the normal are the products of labor, (*b*) the station of the presenting part, (*c*) the fact of compound presentation, as prolapse of the arm, leg or cord, (*d*) fetal deformities

5 The effacement of the cervix, and dilatation of the os

6 The status of the membranes

Of course, in the event that the woman is first seen with labor in progress, all the foregoing data must be determined at the first examination, and may demand a vaginal examination

There may be no question of the expediency of combining external palpation with vaginal examination *in pregnancy*, for then, carefully conducted, in a cleanly manner, the danger is negligible To control the vaginal findings by rectal touch, in pregnancy, will convince the most skeptical of the desirability and reliability of the latter, and will manifest to him the certitude and conclusiveness of the knowledge obtained by it The information obtained by these means, and properly recorded for reference in labor, will determine with definiteness the potential possibilities of the safe passage of the child Therefore, in labor, only the supplemental factors have to be elicited by a pelvic examination — and they may be conclusively fixed by rectal touch

The Pelvis —The configuration of the posterior half of the pelvis may be outlined with clearness, in many respects with a precision that is impossible vaginally The contour of the sacrum, its irregularities and relation to other osseous structures may be determined, the position and movability of the coccyx are evident The spines of the ischia may be palpated, and their influence on labor may be approximated, as in the case of the ischia themselves I cannot concur in Ries' contention that the anterior pelvic half may be palpated as definitely rectally as vaginally Likewise, I have not convinced myself that the diagnosis of pelvic size is easily feasible rectally, though I do not doubt that some resourceful mind will discover a practical means of determining the conjugata diagonalis, even the vera, rectally I have not been able to determine the diagonal conjugate, though the cephalopelvic relationship may be judged with a certain precision

The Soft Parts —Generally, the condition of the soft parts may be determined with the same accuracy as by the vaginal examination, the perineum may be studied with clearness, the texture of the vagina and of the cervix may be readily estimated, and the important data appreciated The progress of the effacement of the cervix may be observed, and the degree of dilatation of the os measured, the clearness of recognition is particularly evident if the cervix is directed posteriorly It is a clinical fact that effacement of the cervix and dilatation of the os occur synchronously in multiparas In primiparas, the rule is for effacement to occur, then dilatation follows Therefore, it is more easy to recognize the degree of dilatation in multiparas In primiparas, the difficulty of appreciation is due to the fact that the thinned cervix fits snugly over the bulging membranes without a thick ring to designate the os As Ries has well pointed out, by palpating the cervix at the height of a contraction, little will be felt, in the interval of contraction, the lessened tension of the membranes will allow an indefinite band to develop which represents the boundary of the os He also shows that the degree of dilatation is of relatively slight importance Its size merely designates, to a certain extent, the progress of labor An emergency which imperatively demands immediate operative intervention is not influenced by the fact that the os is dilated two or four fingers — a dilatation must be consummated artificially The employment of this method has not been occasioned in placenta praevia, but, *a priori*, its recognition by rectal means would be influenced by the same factors which would permit its easy or difficult palpation vaginally Often, a tumor may be outlined better by rectal examination than vaginal

---

[2] Ries, Emil Zentralbl f Gynak April 28 1894

[3] Menge F Winckel's Handbuch der Geburtshulfe, 1, Part 2, p 1208

The Fetus—In the majority of cases the diagnosis of presentation and position may be made without difficulty, providing the presenting part be within the pelvic cavity, that is at least engaged, often, it is surprising with what degree of certainty the sutures and fontanels may be palpated This is especially true after material dilatation has occurred Unquestionably, the facility with which they may be recognized rectally is directly commensurate to the ease with which they may be differentiated vaginally We all occasionally encounter women in whom it is well nigh impossible to recognize the landmarks of the fetal head on account of the advanced ossification, or from marked overriding of the bones the result of excessive molding, or a tense caput, or, finally, the pelvic floor may be so tense that it precludes proper digital exploration In such, when conditions demand certainty of diagnosis, and external palpation is difficult or impossible, the necessity arises of passing the hand into the lower uterine segment, under deep anesthesia, before the position may be accurately fixed In such cases, the rectal offers no more indefiniteness than the vaginal route It has not been my fortune to encounter a compound presentation, during the period I have employed the method as a routine, but I am convinced that it will offer almost the same certitude of recognition as will the vaginal examination, especially if the compound presenting part be laterally or posteriorly directed It has been determined that the maneuvers of Müller and Kerr may be applied through the combined abdominal and rectal palpation when the vaginal is replaced by the latter This is of fundamental importance, in labor, when the woman has a pelvic contraction and it is necessary to determine approximately the cephalopelvic adaptability when a cesarean section is under advisement The station of the presenting part, whether floating, fixed, engaged or deep in the pelvis, all may be as positively estimated by rectal as vaginal examination Ries has found that the pulsations of the cord in the vagina may be felt through the rectovaginal septum Even the still cord may be outlined in the same manner, showing the possibilities in the diagnosis of a prolapsed cord

The Membranes—If there is any distention of the amniotic sac by liquor amnii it is possible to determine the fact In a few instances it has been possible to rupture the membranes by firmly pressing on them through the rectovaginal septum at the height of a contraction If there be a very scanty amount of forewater, or it is practically absent, one necessarily must be kept in ignorance, but it has happened in a few instances (as in oligohydramnios) that the only way to determine the presence or absence of the amniotic sac is to open the vagina widely with specula and inspect the head to ascertain if it be covered with the chorion

Nowhere does the efficiency of rectal examination stand out so distinctly as in the control of women who have a relative indication for cesarean section In such, it is not good obstetrics, usually, to perform the section until by a test of labor it has been positively proved that the disproportion is so material that an intact living child cannot pass We all know that the surest prognostic aid in determining the outcome of a cesarean section is the fact that vaginal examinations have or have not been made within a period of two or three days of the operation It cannot be reiterated too often and emphatically that the contamination produced by one or more vaginal examinations during the labor influences the outcome of a cesarean section more unfavorably than does any other factor except exhaustion or ill-advised attempts at delivery It is possible to determine the nonengagement of the head by abdominal palpation and rectal examination with absolute positiveness therefore, it is utterly needless to enter the parturient canal during the period of watchful expectancy

Rectal examination at or near term is by no means the obstetric limit to the procedure, for it is efficacious at any period of gestation In threatened abortion, or abortion in progress, the rectal touch will furnish many of the data requisite for an intelligent conduct of the case up to the point of operative intervention

TECHNIC

The woman should be given an enema before examination Preferably, she should be on a table, or at least she should lie across the bed in the lithotomy position, with the buttocks quite to the edge, so the gluteal groove will not be in a depression of the bedding A sterile rubber glove should be employed, for even though the finger enters a contaminated cavity it is not good practice to use a glove which may have infective matter on it The finger should be anointed with sterile petrolatum or other unguent, and then should be passed through the anus slowly and carefully At the same time the other fingers should be flexed in order that they may not accidentally enter the vulvar orifice The various movements of the fingers should be slowly made, that the minimum of discomfort may be caused Rarely will there be any pain, even if hemorrhoids are present, in fact, the average discomfort is no greater than when a vaginal examination is made Generally, the rectovaginal septum is so lax that the examining finger may move with great latitude The only time I found the method positively indefinite was in a woman who had had proctitis, with secondary contraction of the wall

DANGERS

Very possibly objections to the method may be developed in the course of a broader experience — objections which may be valid in a very circumscribed field, and limited, in all probability, to conditions in the rectum itself As we now see it, the danger is that the inexpert may allow the fingers or thumb to slip within the introitus during certain manipulations This will be entirely obviated by keeping them flexed The method is contraindicated when the termination of the labor is imminent, for fear, if haste is necessary, the attendant might forget to change the glove, or which is quite as bad, attempt to wash the glove on his hand The glove, after use, invariably should be boiled Preferably, this glove should not be used in the conduct of the labor, even though it has been sterilized by prolonged boiling In the old days when the method was introduced there was an obvious objection to it, as the examining finger necessarily was fouled, and sterilized with difficulty Esthetically, also, it was not agreeable to contaminate the finger with fecal matter Today, with the use of rubber gloves, there can be no such objection

The basic principles on which this paper is founded were obtained in the course of my personal experience and practice In substance they form the essentials of my teaching of pelvic examination in the class room In the obstetric clinical instruction of the students of Rush College, rectal examination is practiced nearly to the exclusion of vaginal examination Those who have charge of this work are convinced that the students have had no sacrifice of a means of teaching since vaginal examinations were eliminated On the contrary, with the increased license of examination, the students have had an increased opportunity of pelvic investigation

Since Dr N Sproat Heaney introduced this procedure in the dispensary clinic, the students have enormously augmented their practical knowledge of the phenomena of labor — are infinitely better placed than were the students who were permitted to make a limited number of vaginal examinations in a former period

CONCLUSIONS

1 The discovery of the possibilities of rectal examination in labor by Kroenig and Ries is one of the most important contributions to modern obstetric medicine of the last generation

2 There must be a complete revision of the chapter on pelvic examination in obstetric textbooks Adequate presentation of the value of rectal examination must be stated Vaginal examination should be made subordinate to rectal touch

3 While, at the present time, rectal examination does not give us the means of measuring pelvic size, it is of great value in estimating the factors situated in the posterior half of the bony pelvis

4 In almost every direction, under appropriate conditions, rectal examination is as definitive as vaginal, if combined with abdominal palpation

5 The ease or difficulty of rectal examinations are commensurate to the ease or difficulty which encompass the vaginal ones, and are dependent on the same factors

6 Rectal examination is an utterly innocuous procedure in labor, whereas, vaginal examinations are always potential sources of infection to the woman

7 Rectal examinations are peculiarly appropriate to those women who are to receive the test of labor in relatively contracted pelves when a cesarean section may possibly be needed

8 Vaginal examinations should be made in labor
only whepaifs· some special reason, the rectal findings
the perineum, (b) 'nconclusive
(d) recognition of it can be said of rectal examination
ment — placenta praee conduct of normal labor with the
of vaginal examinations a decided

THE RAT A CARRIER OF A DYSENTERIC AMEBA *

KENNETH M LYNCH, M D
CHARLESTON, S C

The purpose of this communication is to record observations incriminating the rat (*Mus norvegicus*) of a possible new rôle in the dissemination of disease, the details of which go to show that

1 The rat (*Mus norvegicus*) suffers from spontaneous amebic dysentery similar to that occurring in man

2 This apparently occurs in endemic foci in Charleston, S C

3 The ameba found in the cases of rat infection here reported are indistinguishable from *Endamoeba histolytica*

4 This rat may be infected with *Endamoeba histolytica* by allowing it to eat human feces containing this parasite

5 The disease thus produced is practically the same as that occurring in man and from spontaneous infection in rats

6 This infection, spontaneous and experimental, may be transmitted from the infected to the healthy rat by close association, that is, living, eating and drinking together

7 The rat is a possible and probable disseminator of dysenteric amebas pathogenic for man

The details of the study from which these conclusions are drawn are as follows

During the course of experimental transmission of the *Trichomonas intestinalis* to rats by feeding them human feces containing these parasites,[1] a large brown rat was given feces containing *Endamoeba histolytica* in addition to the trichomonas At the end of three weeks the rat was noticed to be getting thin in spite of good feeding, and to be sluggish whereas he had been active and vicious His emaciation became more noticeable in the course of a few days, and at the end of a month he appeared to be very sick and had developed a mucous diarrhea This passed fecal matter, when examined fresh and warm, contained, in addition to the trichomonas and leukocytes, desquamated epithelium and shreds of intestinal mucosa, and red blood cells, numerous active and resting amebas identical with those in the feces with which he was fed His feces as well as that of all the other animals used in this study had been examined for amebas before feeding and none found His symptoms, sluggishness dyspnea, turning of the hair, loss of appetite and diarrhea continued until he died on the thirty-second day after feeding

Postmortem examination revealed a general anemia, acute mesenteric lymphadenitis, late perilobular cirrhosis of the liver with microscopic periportal abscesses in which no cells like amebas were found, jaundice of the liver and kidneys The condition of the liver was probably due to the extensive infiltration with cysticerci and secondary infection The following was the condition of the alimentary canal

Stomach Considerable mucus formation, otherwise normal

Small intestine Distinct acute catarrhal enteritis, fluid mucinous contents, no ulceration, no amebas present but many lamblias

---

* Read before the Medical Society of South Carolina Nov 15 1915

[1] Lynch K M The Trichomonas as a Parasite of Man and Certain Lower Animals, Tr Pan American Med Cong, 1915

Cecum. Semifluid yellowish mucinous contents containing the *Trichomonas intestinalis*, epithelium and mucosal portions, red blood cells, leukocytes, and large numbers of active and encysted amebas. The wall was the seat of an acute ulcerative inflammation practically identical grossly and microscopically with the more acute type of human amebic colitis, with irregular ragged undermined acute ulcerations, having necrotic edges and containing fecal matter and granular detritus in which the amebas were very numerous, and between which the mucosa was the seat of an acute catarrh.

Remainder of the large intestine. Acute catarrhal colitis, no ulcers, contents the same as that of the cecum.

The amebas in this animal and in the feces with which he was fed were recognized as *Endamoeba histolytica* by the following distinguishing features, according to Craig:[2] Size, from 20 to 60 microns, pseudopodia, large and blunt or slender finger-like, active, ectoplasm distinct, nongranular, refractive, endoplasm, granular, containing numerous noncontractile vacuoles and occasionally a red blood cell, nucleus indistinct, when at rest possessing a distinct clear shell enclosing the hyaline refractive body, with Wright's stain, ectoplasm dark blue, endoplasm light blue, nucleus pale red or pink.

This occurrence brought to my mind the habits of the rat, and his liking for feces and also for almost any and all of our food and drink. Failing to find any record of experimental transmission of dysenteric amebas to rats, although it has been done with other animals, notably kittens,[3] I instituted experiments to determine whether it could be done with any constancy by feeding, as this method alone could be of importance in incriminating the animal of possibly disseminating the infection.

To date I have fed about twenty rats with feces of as many human beings containing dysenteric amebas, active and in the resting stage. These include both the brown rat and the pet white rat (*Mus norvegicus*). Four of these have followed the same course as the first, that is, at about the end of the first month after feeding, they became sick, showing dyspnea, loss of appetite, emaciation, turning of the hair, and sluggishness, and developed a mucous diarrhea from an acute ulcerative inflammation of the cecum and acute catarrh of the remainder of the intestine. Some of them died after a few days of the well-marked symptoms, while others were killed for purposes of better study. Amebas identical with those administered were recovered from the large bowel, particularly the cecum, to which the ulceration was limited. While all of them exhibited this ulceration of the cecum, in some it was more severe and diffuse and acute than in the others and in the usual human case. None have shown any involvement of the other organs except in the nature of toxic degenerations. Three of these rats were white and the fourth brown.

What will occur in the remainder of the animals under experimentation remains to be seen, as none have yet arrived at the usual time of onset of symptoms.

In order to determine whether the infection could or would be transmitted from rat to rat, feces of the first were fed to another, and this one became sick with the usual symptoms at the end of two weeks, exhibited the ameba in stools and cecum, died shortly and showed an acute diffuse ulcerative inflammation of the upper large intestine. Sufficient time has not yet elapsed to show whether the third in this series, which was fed the feces of the second, will suffer in like manner. Also, a noninfected rat was placed in the cage with one which had been fed, but some time before it developed any symptoms of disease, to see if possible contamination of food and drink would infect the other. One of these developed the disease and died of it ten days after its fellow had suffered a like fate.

For the purpose of obtaining wild rats for the work, and also with the hardly formulated idea of searching for spontaneous amebic infection, these animals were trapped in different sections of the city of Charleston. The first source, a grain house on the water front, proved free of the infection. I have had about fifty rats from this place, have killed a number for examination, and failing to find amebas in them, have selected all those used for the feeding experiments from this source.

The first rat caught at the second place and brought to me after it had been killed exhibited as typical an example of amebic inflammation of the cecum as I have seen in a human being. Other than being less acute, and it must be remembered that the animal did not die of it, the lesion was practically the same as that seen in the first experimentally produced. The ulceration was limited to the cecum, was of irregular serpiginous character, undermined, with ragged edges, contained granular material and fecal matter, and the intervening mucosa was the seat of a subacute catarrh. The small intestine was not altered, and the lower large intestine had suffered a very mild catarrh. The content of the large bowel was softer than usual, but the stool well formed.

An ameba indistinguishable from the *Endamoeba histolytica* was present in the large intestine, a few in the rectum, many in the cecum, and large numbers in the material from the ulcers. It possessed the characteristics in size, activity, differentiation of ectoplasm from endoplasm, indistinctness of nucleus, appearance of pseudopods, resting stage, and staining properties. After direct comparison of the parasite obtained from this rat, and from others hereafter mentioned, to *Endamoeba histolytica* from human beings and experimentally infected rats, I am unable to tell them apart and conclude that it was *Endamoeba histolytica*.

The house in which this rat was caught was a negro habitation in a negro community, and while it had water closets and sewer connections, unfortunately these things do not always mean proper sewage disposal among these people and in such houses in Charleston. I have learned of a house within a few numbers of this one in which the water closet had been out of use and the several families living there using a basement for the purpose for some time. I also know of a case of amebic dysentery which came from this locality, apparently originating there. The suggestive relationships are obvious.

From this place, I have since obtained another rat in the same condition as the first, and from feeding the cecal contents of the first to two young white rats, have been able to produce the same condition in them as occurred in the previously described experimental infections from human feces, the same colitis, diarrhea and ameba, and death at the end of about one month.

[3] Sellards, A. W., and Baetjer, W. A.: Bull. Johns Hopkins Hosp., February, 1915, p. 45.

From two other localities of similar nature but in different parts of the city, I have obtained five other rats with amebic colitis, one from one place and four out of six obtained from the other. In these five the ulcers were small, irregularly rounded, with elevated undermined edges, only from three to six or eight in the cecum, and the remainder of the intestine normal. The same ameba was present, mainly in the resting stage in the rectum, but active in the cecum and especially in the ulcers. In another of the six, the ameba was present, and although there was some desquamation of epithelium and catarrh of the cecum and small points of microscopic erosion of the mucosa, there were no gross ulcers. None of these rats exhibited amebic infections of other parts of the body.

I am now undertaking a search for the extent of the distribution of this spontaneous infection, both in the city and in the rural districts, and am also looking for possible human endamebic intestinal infection from the same localities, an indication of which is already given in the case from the second place mentioned.

At the same time the experimental work will be continued and any further observations made known.

The *Endamoeba histolytica* is a frequent inhabitant of the intestine of the negroes in Charleston. The possible relationship is interesting.

The rat has a liking for human feces and he is no respecter of our food and drink. Stiles[4] believes that man may become infected with lamblias through eating food which has been soiled by the excrement of rats. The important possibility of the same manner of transmission of dysenteric amebas to man is obvious.

Stiles fails to mention any knowledge of amebas in rats, neither have I found it recorded from any other source.

The burden of the sins of the rat and this menace to the health of man seem certainly increased by the incriminating evidence included in these observations.

SYPHILITIC IRITIS WITH CONDYLOMAS

REPORT OF THREE CASES

WALTER BAER WEIDLER, M.D.
NEW YORK

The three cases here presented are of such a nature that many authors would regard them as gumma of the iris, but as all of these lesions were seen during the secondary stage of syphilis, it would seem that they should be more properly diagnosed and classified as papules or condylomas of the iris.

Papular iritis is often called iritis gummosa. This is because papules of the iris were always regarded anatomically as gummas, and it is often impossible to differentiate between these syphilitic formations even with the microscope. I believe that in the very virulent or malignant form of syphilis, it is possible to have true gumma of the iris during the secondary stage. It would seem that it is more a matter of size and the period of its appearance that makes one lesion a papule and the other a gumma. It is my opinion that gummas are rarer than papules. The papules often occur in numbers, whereas the gumma is single and perhaps more often seen near the ciliary body.

Case 1.—Mr. J. T., aged 45, chauffeur, had chancre of the penis seven months before he came to the Manhattan Eye and Ear Hospital, Dec. 2, 1913, with the history that for the past ten days the left eye began to be red and painful. He had no treatment for the eye conditions and only a short period of treatment for the syphilitic infection. There was considerable photophobia and lacrimation, and the lids of the left eye were kept closed. There was considerable haziness of the cornea, more pronounced in the lower half. There was a very severe congestion and engorgement of the superficial and deep ciliary vessels, giving a violaceous color to the pericorneal region. The iris was muddy and discolored. The pupil was contracted and did not respond to light, accommodation or convergence, but the tension was normal. The vision was reduced to counting of fingers at 3 feet. There was a condyloma of the iris down and in, and it seemed to be in the anterior portion of the iris stroma. It was grayish-yellow, about 5 mm. at its base, extended forward in the anterior chamber and was in contact with the posterior surface of the cornea. There were a number of small blood vessels visible over the growth.

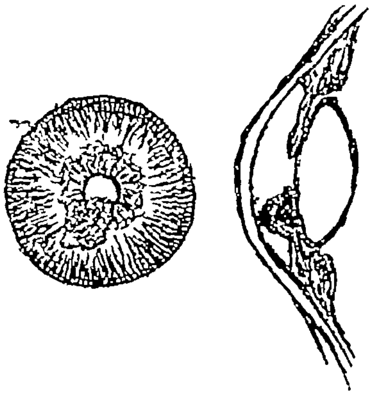

Fig. 1.—Left eye, growth was down and in reaching forward to posterior surface of the cornea. Pupil contracted and did not respond to light.

The Wassermann test was positive (++++). The patient refused to have an injection of neosolvarsan, and was put on the iodid-mercury treatment, and after ten days the mass began to get smaller, the pupil began to dilate somewhat, the cornea was entirely clear, the bulbar congestion was much less, and the iris about the same color as its fellow. The condyloma or papule reduced to one fourth of the original size, and two weeks later the eye was absolutely quiet within a vision of 20/70.

Case 2.—Mr. L. M., colored, aged 23, elevator man, gave the history of having chancre on the penis seven months previous, and has been under treatment for syphilis at St. Luke's Hospital, receiving mercurial injections. Presented himself at the Manhattan Eye and Ear Hospital, Feb. 27, 1914, stating that twelve days before the right eye began to give him pain and this was accompanied with photophobia and lacrimation. He had no treatment at any time for the eye conditions. There was at this time considerable swelling of the lids with marked photophobia and lacrimation. The cornea was clear, there was a very pronounced pericorneal injection, and the deep ciliary vessels were very much engorged. The eye was very tender over the ciliary region. The aqueous was clear, the anterior chamber normal, and the general appearance of the stroma layer of the iris was unchanged, except up and out, where the stoma was decidedly elevated. At the pupillary edge of the iris, up and out, there was a whitish-gray exudate which seemed to protrude between the stroma and retinal pigment layer of the iris. This exudate had apparently attached itself to the anterior capsule of the lens, and the mass was protruding forward into the anterior chamber about 3 mm. There was only this single papule or condyloma with slight or no inflammatory changes in the iris. The vision of the right eye was 20/40 ??, of the left eye 20/20. The pupil was 3 mm. and did not react to the light, showing the presence of synechiae. The von Pirquet was positive, and there was the history of one of his brothers dying of tuberculosis. The Wassermann test was also positive (++++).

March 15, 1914, neosalvarsan was given, and the photophobia, lacrimation and pain entirely disappeared in thirty-six hours. The superficial and deep injection was much less. The tumor mass was rapidly reduced to at least two-thirds its former size, and the pupil dilated fully and freely There are still the synechial remains on the capsule of the lens, but no trace of the condyloma remains

---

[4] Stiles, C. W.: The Rat and Its Relation to Public Health, Publication *U. S. P. H. S.*, 1910, p. 89.

Case 3—Mr P E, aged 26, Irish, gave a history of having chancre about three months before and had taken treatment for syphilis for a few weeks He came to my clinic at the Manhattan Eye and Ear Hospital There was some swelling of the lids of the right eye, marked pericorneal injection involving the ciliary vessels The cornea was slightly hazy and the aqueous cloudy The iris showed effects of inflammation being discolored and the pupil 2 5 mm Down and out there was a circumscribed elevation about 3 by 4 mm at its base and about 2 5 mm high, extending forward toward the posterior surface of the cornea but not in contact. This mass was pinkish-gray, and no distinct vessels were noted, but there was apparently some synechia formation There was some photophobia and lacrimation The Wassermann test was positive (++++) Two days later neosalvarsan was given and after thirty-six hours a decided decrease in the size of the condylomas was noted Inside of four days there was almost complete absorption of the mass The iris cleared and the inflammatory symptoms were entirely relieved. A small synechia remains on the outer side of the iris above the location of the condyloma

The very rapid response of this special syphilitic lesion in Cases 2 and 3 to the neosalvarsan was remarkable, and its use would seem to be especially indicated in this sort of syphilitic manifestation

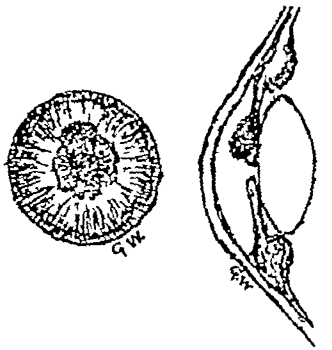

Fig 2—Right eye growth was up and out but did not reach to the cornea as in Figure 1 There was a grayish white exudate between the retinal pigment layer and the stroma of the iris

The diagnosis of the syphilitic lesions of the iris has been made much easier and surer by means of the serologic test Where a definite history of the syphilis can be obtained, diagnosis of these lesions is a simple matter, but in the cases in which such a history is not obtained, the Wassermann reaction has added a most important factor in the diagnosis It might be well to mention here that at times it has been difficult to differentiate between a papule or condyloma and a tubercle of the iris It is in this sort of a case that the von Pirquet test and the subcutaneous tuberculin test become of great importance Recently I have seen several cases of tubercle of the iris which have been treated for syphilis of the iris in spite of a negative syphilitic history and a negative Wassermann reaction with no improvement For those who have not been especially interested in the tuberculin tests and therapy, I can readily see why such a line of treatment would be persisted in It might be argued that previous antisyphilitic treatment has been employed, hence the negative Wassermann, or that the patient may deny syphilis for reasons best known to himself, and therefore without any further search for the cause, antisyphilitic treatment is used

The microscopic examination of the iris and the ciliary body when affected with gumma or condyloma reveals about the same changes as are noted in chronic inflammation of these tissues There is nothing definite and characteristic which would make it possible to say that syphilis was the factor which caused the growth The blood vessels show fairly constant involvement and microscopic changes in syphilis of the iris There is an endarteritis especially of the smaller vessels with an apparent increase of the endothelial cells This is partly due to the increase of pressure on the highly sensitized cells which line the lumens of the vessels The adventitia also shows a proliferation or new deposition of cells with a marked increase of epithelioid cells outside of the adventitia

Fuchs found the iris of normal thickness infiltrated with round cells, and these chiefly in the anterior limiting membrane This inflammatory exudate of the leukocytes was also in the reticulum, and in some of his cases he found typical giant cells present The presence of giant cells has been noted by other observers, but in none was there any caseation present There are always a number of capillaries seen inside or around these syphilitic nodules, which is not the case in the tubercular nodules of the iris

SUPPURATIVE CHOLECYSTITIS FROM THE PARATYPHOID BACILLUS

REPORT OF A CASE

LUCIUS E BURCH, M D
Fellow of the American College of Surgeons Professor of Gynecology and Dean Vanderbilt University Medical Department
NASHVILLE, TENN

History—The patient is married, aged 25, occupation electrician His family history is unimportant, except that he had one aunt on the paternal side who died of tuberculosis at the age of 40 He had the usual diseases of childhood, including spinal meningitis He never had pneumonia typhoid fever, tonsillitis or rheumatism. At the age of 13 he developed malaria of the tertian type, which recurred for three summers He uses tobacco to excess and occasionally beer and whisky Venereal history is negative About once a year he becomes badly constipated, and this is usually associated with cramps in the abdomen These cramps continue for several days, unless relieved by a purgative His digestion has always been perfect. There is no history of any accident or injury, although he has a cataract of his left eye, which has produced a loss of sight in that eye

Monday morning Aug 16, 1915 he went to his work in his usual good health In two hours time however, a severe headache came on which was followed by pain in the abdomen and this in turn by nausea He continued at his work however, for the remainder of the day and returned home about 5 30 p m About 6 o clock the pain in the abdomen was so severe that he called his physician Dr W E Reynolds After making a careful examination Dr Reynolds told him that his symptoms were suspicious of intra-abdominal trouble, and asked to bring in a surgeon as a consultant to which the patient consented I saw the patient for the first time in consultation with Dr Reynolds about 9 p m He was then complaining of pain on the right side of his abdomen The temperature was 102 and the pulse was 100 An abdominal examination showed a marked rigidity of the right side and a localized tenderness most acute midway between the navel and costal margin about 2 inches from the median line He had however some tenderness all over the right side. The symptoms were rather suggestive of appendicitis, but we decided to wait until morning Meanwhile he was ordered to abstain from all food, liquids or medicine He continued to suffer in the night, and the next morning when his physician saw him, a localized pain was found in the region of the gallbladder This pain continued with moderate severity during the forenoon. When the physician examined him again at midday, it was discovered that the localized pain had shifted from the region of the gallbladder to the region of the appendix. The temperature at this visit was 101, and the pulse had gone up to 120 He was advised to go to the hospital for a more careful study of his case, and an operation, if necessary

He was brought to my infirmary about 8 p m His pain was somewhat better, although there was a marked rigidity on the right side and a point of acute tenderness two finger breadths beneath the costal margin on that side A urinalysis was made, which was negative Blood examination revealed hemoglobin 85 per cent, white blood cells 12,000 Temperature, 99 6 We had now had the case under observation for twenty-four hours, and as no appreciable improvement was present and as the symptoms were very suggestive of an intra-abdominal lesion, either the appendix or the gallbladder, an operation was advised, to which the patient consented

Operation and Result—A right rectus incision was made in order that a thorough exploration could be carried out The appendix was enlarged and somewhat inflamed We felt, however, that this could not be the entire cause of the trouble, and further search of the abdominal viscera was instituted, although the appendix was removed The gallbladder was found in a state of marked distention It was quite red, covered with lymph in numerous areas, and on the fundus were several small patches that were almost black A needle was introduced, and about 5 ounces of cream-colored pus were drawn off The gallbladder was then packed off, opened, cultures from the interior were taken, and a drainage tube inserted and the abdomen closed The next morning the patient stated that he had been perfectly comfortable since he regained consciousness The temperature, however, was 102, but the pulse had dropped to 100 The drainage from the gallbladder was copious and of a black color

For the next few days the patient continued to feel well His abdomen was flat and he complained of no pain at all except a headache The temperature continued to run between 103 in the afternoon to 101 in the morning On the fifth day after the operation the temperature was 104 and a blood count was made which was as follows red blood cells 6,200,000, white blood cells 8,000 A careful examination of the patient's throat, lungs and abdomen was made, all with negative result The Widal was also negative The laboratory report at this time had not been received, and for this reason we were unable to account for the continued temperature with almost a normal blood count The temperature continued to drop gradually, and reached the normal on the morning of the tenth day after the operation It continued to run up in the afternoon for four days, ranging from 99 to 100 2 Fourteen days after the operation, for the first time, the temperature remained normal for the whole twenty-four hours, and continued to do so for the remainder of the patient's stay in the hospital The wound healed by first intention, the tube was removed at the end of the tenth day, and the drainage tract was closed at the end of three weeks At the end of five weeks and a half the patient returned to his business, feeling in first-class condition, although a little weak

Laboratory Report—The following report was received from the Department of Bacteriology, Vanderbilt University, Medical Department

"Cultures made from the pus obtained from the gallbladder showed that there was but one organism present This organism was found to be a short bacillus, irregular in length, actively motile, and gram-negative When grown in litmus milk the medium became acid after twenty-four hours, but by the twelfth day had become alkaline again The milk was not coagulated There was marked gas formation after twenty-four hours in glucose bouillon On Russell's medium the surface was bluish-white in appearance, while the lower layer became red and contained considerable gas On endomedia the colonies formed a pale, bluish-white, translucent growth

"The bacillus was not agglutinated by stock serums which had been obtained from patients suffering from infection with the typhoid bacillus and with the paratyphoid bacillus B, but was strongly agglutinated by the serum from a patient suffering from infection with the paratyphoid bacillus A.

"The serum of the patient did not agglutinate stock culture of the typhoid bacillus or the paratyphoid bacillus B, but did agglutinate the paratyphoid bacillus A, in a dilution of 1 200

"From the cultural reactions and the agglutination tests, the organism isolated in pure culture from the pus is probably the paratyphoid bacillus A"

COMMENT

The interesting feature of the case was the early involvement of the gallbladder, as the first symptoms presented by the patient were due to the cholecystitis I am unable to find in the literature of paratyphoid how early and how often cholecystitis occurs With the typhoid bacillus it is not unusual, but comes up later in the disease I am of the opinion that a careful culture made in all cases of noncalculous suppurative and gangrenous cholecystitis will clear up, to a great extent, the uncertainty concerning the etiology that now exists in these conditions

---

PAINFUL WEAK FEET

REPORT OF CASE

H Winnett Orr, M D, Lincoln, Neb

Many persons with very flat feet have no discomfort whatever They have no foot strain, and strain is what causes all, or nearly all, the distress and secondary symptoms in these cases Conversely, in those who have pain, to relieve the strain is to cure the patient Usually, a period of rest, a change of shoes (especially shoes that are too tight, too narrow, or too short) "arch supports," or more scientifically constructed braces, or a combination of several of these measures, will afford the patient great relief I encounter a considerable number of patients, however, who have tried all of the above methods and who are still not relieved

CASE REPORT

History—A young man, 23 years of age, consulted me last July with a history of disability on account of painful feet, which had been increasing for about three years From January to July, 1915, he had been able to do only three weeks' work at his trade, that of a foundryman His feet were swollen and acutely tender He had leg ache, with pain in the knees and hips At times there was much cramping of the muscles of the legs—so much sometimes that he could not sleep at night He had a family dependent on him and was extremely anxious to resume work The feet were markedly everted and there was pronounced spasm of the peroneal muscles He came to me seeking braces, but I dissuaded him from this and advised tenotomy of the peronei with a period of fixation of the feet in inversion in plaster of Paris

Operation—He accepted this advice and the operation was done the next day An attempt to forcibly invert the feet under anesthesia before tenotomy was not successful Accordingly all of the peroneal tendons were divided just back of the external malleolus and then the feet could easily be strongly inverted

Plaster casts were put on with the feet in this position and the patient kept in bed for about two weeks Then he was allowed to get around, still wearing casts for a total of six weeks During the seventh week after operation the casts were removed, ordinary shoes were put on, and he went home

Result—He now (November, 1915) reports that at first he walked with his feet in an extremely inverted (overcorrected) position, but that there is only a slight tendency in that direction in one foot at present

He stands and walks perfectly well and can even walk on tip toe (an impossible feat for most of these patients) He also relates that one day recently he husked corn for an entire afternoon He wore ordinary shoes, following the wagon over rough ground with no discomfort except that he felt a little tired afterward

He is resuming his work as a foundryman less than four months after operation and following three years of great disability

A comparison of results by this method with those of other methods—especially forcible correction without tenotomy—leads to the conclusion that peroneal tenotomy (or perhaps still better, resection of a portion of the peroneal tendons as suggested by Robert Jones) is much superior The operation must of course, be carefully done under strict asepsis and the after-care faithfully carried out or it will not fully succeed If properly done however, great relief may be had for a class of patients who suffer great distress and extreme disability and who will not be relieved in any other way

---

REPORT OF A CASE OF MERCURIC CHLORID POISONING

WITH PARTICULAR REFERENCE TO ITS TREATMENT

HARRY M. KAY, M D MADISON WIS

C. W man aged 47, July 3 1913 at 2 p m took five tablets 7½ grains each of mercuric chlorid. Fifteen minutes after taking this drug he was attacked with a desire to vomit and barely reached the toilet room when violent vomiting began Three or four spasms occurred at the same time and profuse perspiration started This continued for about fifteen minutes when there was a respite of about ten minutes Then another attack of violent vomiting occurred, this attack being accompanied by simultaneous involuntary movements of the bowels This lasted for about thirty minutes His mouth began to fill with frothy saliva which when expectorated would remain connected to the mouth by a silver thread Attacks of vomiting and diarrhea less violent, continued to recur at longer intervals The movements of the bowels took place at intervals of fifteen or twenty minutes About 8 p m., the patient drank some cold water, which seemed to give him considerable relief During the entire night, he was subject to occasional spells of vomiting and involuntary movements of the bowels.

July 4 vomiting was much less frequent. The bowels still moved involuntarily, and there was continuous salivation Sweating ceased during the night. Cramps did not recur The patient drank some lemonade at noon and again at night, this seemed to give him considerable relief

July 5 the symptoms continued, but were less violent, vomiting occurring but four or five times a day In the morning the patient drank a pint of cold milk, at noon-time he took lemonade, between times ice-water, at evening a bottle of beer

July 6 vomiting had almost ceased. There was one movement of the bowels

July 7, the patient felt considerably better There was one attack of vomiting Salivation still continued The bowels moved about every hour, the stools were of the consistency of mucus and blood. Defecation was painful.

July 8, the patient did not vomit. The diarrhea was continuous The stools were bloody as on the previous day

The foregoing history was obtained from the patient two months later

July 8 five days after he had taken the poison I was called to see the patient. His appearance much resembled that of a person in a uremic condition. He was semiconscious, he would answer an occasional question and go back to his partial slumber, the pulse was 120, temperature 99 4 and respiration 12. The patient gave me a history of *complete anuria for five days*

The patient was taken to the hospital. On arrival he was immediately given a hypodermoclysis of 3 000 c.c. normal salt solution and put in a hot pack for twenty minutes Catheterization resulted in 1 ounce of bloody urine There was a good reaction from the skin Profuse perspiration lasted about half an hour During the night the patient slept very little One of the troublesome complications with which we had to deal was hiccups, the patient hiccuped constantly during four days and nights, this was controlled somewhat by an occasional hypodermic of 1/100 grain of nitroglycerin

July 9 the patient was again catheterized, and 2 ounces of urine resulted Examination showed a faint trace of albumin, and a few pus cells and blood cells There were no casts Specific gravity was 1 008

Every day for the ten following days, he was given from 2 000 to 3 000 c c normal salt solution hypodermoclysis and about the same quantity of normal salt solution proctoclysis Following the hypodermoclysis daily, the patient was put into an electric bath cabinet for from twenty to thirty minutes The reaction of the skin was very marked The patient was returned to bed and placed between blankets and the perspiration continued for two or three hours The patient was catheterized the first three days but on the fourth day he voluntarily voided 4 ounces of urine. The examination of this urine showed considerable albumin, and many granular and hyaline casts The blood pressure at this time was 180 mm

On the fifth day, the patient voided 10 ounces of urine on the sixth day 15 ounces and on the seventh day 20 ounces From then on the voidance of urine was about normal The continuous examinations showed albumin and also numerous hyaline and granular casts When the normal flow of urine was established, he experienced relief from considerable pain in the region of the kidneys which had persisted since the early stages of the case.

During the first two weeks of his stay at the hospital it was necessary to give considerable attention to the condition of the bowels The first few days there was a constant diarrhea the stools having the consistency of mucus and blood This we tried to correct with large doses of bismuth subnitrate and sodium bicarbonate Later, constipation followed and was treated with mild enemas

The mouth also was a source of great trouble. Fortunately the patient had a partial plate which was removed and the gums treated. There was also constant salivation Burning of the mouth was treated with alkaline mouth washes and also some potassium chlorid solution The cardiac weakness and special symptoms were treated according as they developed No morphin was given at any time Occasional doses of 5 grains of veronal were given

Diet consisted of milk, egg albumin, cereals cream toast, etc.

The patient left the hospital July 22 apparently in good condition The urinary examination at that time showed traces of albumin a few blood cells and an occasional granular cast Blood pressure was 130 mm leukocytic count 8 000 red cells 4 300 000 Two weeks after the patient s discharge he was back at his work About a year after his discharge I was fortunate enough to procure a specimen of urine Examination showed that there remained no ill effects from the poison I have not seen him since but recently heard that he is in Milwaukee going about his work regularly and apparently in perfect health

I wish to acknowledge my indebtedness to Prof. A. S Loevenhart and Dr Leopold Schumacher for their assistance and cooperation during the progress of the case

---

Tuberculosis Number—The September number of the Illinois *Health News* the official monthly bulletin of the Illinois State Board of Health is devoted entirely to the cause prevention and cure of tuberculosis. The pamphlet s written for the benefit of the laity among whom it is intended to circulate and recites in easily understood language the facts concerning this disease It contains a number of pointed cartoons which emphasize various phases of the tuberculosis problem that should appeal strongly to the readers of the bulletin Emphasis is laid on the danger of employing or depending on any so-called cures for consumption done up in a bottle

Therapeutics

TUBERCULOUS MENINGITIS

Before discussing this almost hopeless disease, a review of our present knowledge of the physiology of the cerebrospinal fluid will enable us better to understand the causes of, and the danger from, cerebrospinal pressure

We may epitomize our knowledge of this fluid as follows

1 The cerebrospinal fluid is a secretion of the cubical cells of the choroid plexuses of the lateral ventricles and of the perivascular lymph spaces[1]

2 Some barrier prevents most medicaments from reaching the cerebrospinal fluid by way of the blood stream, though bile pigments and sodium salicylate have been found in the cerebrospinal fluid

3 The whole normal quantity of cerebrospinal fluid may be secreted in three or four hours[2]

4 Normally the fluid has free passage from the lateral ventricles to the third ventricle, then through the aqueduct of Sylvius to the fourth ventricle, and from there is distributed through foramina into the subarachnoid space, and from this reservoir over the cerebrum, the cerebellum and downward into the spinal arachnoid

5 The fluid is absorbed from the cerebrospinal canal by both blood and lymph vessels, but is mostly taken up by the veins, hence any obstruction to the venous circulation in the brain or meninges is more serious than a lymphatic obstruction in the same region

6 A slowly developing cerebral pressure (compression) is better tolerated than a rapidly developing pressure Also, rapid loss of pressure (decompression) is often dangerous There is danger, therefore, from too rapid injection of an antitoxin or other fluid, and there are sometimes serious consequences from a too rapid withdrawal of cerebrospinal fluid

7 The symptoms of any form of meningitis are due to the toxins of the germ infection plus increased cerebrospinal pressure If this pressure is sufficient to cause coma, repeated spinal puncture will relieve it, and such drainage is theoretically indicated Of course, in spite of the relief from such pressure the patient may die of toxemia

8 Phenol (trikresol) preserved serums for intraspinal use have some elements of danger, although they are used with impunity by some clinicians

9 Brain tumors mostly cause increased cerebral pressure, not by their growth or by local pressure, but by obstructing venous drainage of the cerebrospinal fluid[3] Edemas of the eye grounds and choking of the disks seem to be caused by pressure in the optic nerve sheath, due to venous obstruction

10 Dandy and Blackfan[4] have shown that hydrocephalus may be of two types, due either to an obstruction to the outflow from the ventricles, or to decreased absorption from the subarachnoid space They also have found that there is but little absorption of surplus fluid in the ventricles Hence if absorption is delayed in the arachnoids, operative interference gives no outlook of success

Meyers[5] has given a numerical classification of the etiologic factors, symptoms and signs of 105 patients with tuberculous meningitis A brief review of these factors will be of interest As to sex, they were equally divided The ages varied from 5 months to 11 years, with about one-third of the patients between the ages of 2 and 3, while over half were between the ages of 2 and 5 The greatest number of these cases occurred in January and March (in Boston) The variations in the number of cases occurring in the different months would probably change somewhat with the region and the climate investigated, therefore a monthly analysis is of but little value Meyers found that 38 per cent of these children had had no previous diseases, in the remaining 62 per cent measles had occurred more frequently than any other disease The average duration of the disease from the time of the beginning of symptoms was seventeen days Meyers thinks the disease is not so rapidly fatal as it once was on account of lumbar puncture being now more frequently done, thus preventing early deaths from cerebral pressure

Lumbar punctures were done from one to seven times to a single patient He finds that lumbar puncture prevents convulsions, which become rare in the clinical history of the disease thus treated Meyers believes that the advantage of lumbar puncture is not only in relieving pressure, but also in eliminating a certain amount of toxin He has not found unpleasant symptoms to occur from the withdrawal of even a considerable amount of spinal fluid, even though it was not under high pressure

The rule of Meyers is to allow the spinal fluid to drain until it runs at the rate of from 10 to 12 drops per minute, and to draw off from 20 to 30 c c of fluid, depending on the pressure Eighty per cent of the cases showed increased pressure, but varying of course, in degree If the child lived, lumbar puncture was done once every forty-eight hours If the fluid removed at the first puncture did not show the organism causing the meningitis, the later punctures usually did, and tubercle bacilli were found in 21 5 per cent of these 105 cases of tuberculous meningitis

When there was no increase of pressure in the cerebrospinal canal, there were almost no disturbances of the reflexes, and there seemed to be no relation between the amount of pressure and the presence of convulsions, bulging fontanel or retraction of the head The fluid in this disease was never found really turbid, and was generally absolutely clear The cell count of the fluid varied from 24 to 960 per cubic millimeter, with an average of 198 This cerebrospinal fluid cell count seems to vary with the leukocyte count of the blood the greater the leukocyte count, the greater the number of cells in the spinal fluid The prevailing type of cell in the spinal fluid was the small mononuclear, ranging from 90 to 100 per cent in 67 per cent of the cases, and from 80 to 90 per cent in 20 per cent of the cases A fibrin clot was found in 70 per cent of the cases, and a positive globulin test in about 50 per cent The globulin content seems to vary directly with the cell count The first part of the spinal fluid withdrawn at each puncture has a different cellular content from the last part that is withdrawn, the first part giving the greater number of cells

[3] Frazier New York Med Jour, June 27, 1914

[4] Dandy, W E, and Blackfan, K. D Internal Hydrocephalus, Am Jour Dis Child, December, 1914, p 406

[5] Meyers A E A Study of 105 Cases of Tuberculous Meningitis, Am Jour Dis Child, May, 1915, p 427

One fourth of the cases showed a leukocyte count of the blood between 10,000 and 15,000, the lowest count was 8,500, and the highest 48,000 Absence of eosinophils, as in some other diseases, is considered an unfavorable symptom

In those tested for the von Pirquet reaction, 63 per cent were positive

Twenty-five per cent of the cases gave a history of definite exposure to tuberculosis Thirty per cent of the cases showed lung involvement, and had more or less cough In 71 per cent the eye reflexes were abnormal, but in 29 per cent the pupils were equal, and reacted normally to light Thirty per cent showed normal patellar reflexes, and in 21 per cent the reflexes were absent There was a positive Babinski in 21 per cent Fifty per cent of the cases gave the Oppenheim sign Ankle clonus was rarely present Kernig s sign was present in 27 per cent of the cases Forty-three per cent showed some signs of paralysis, with strabismus as the most frequent form Seventy per cent showed some rigidity of the neck, and, late in the disease, there was definite stiffening of the limbs

While 39 per cent of the patients had a history of convulsions before entering the hospital, as stated above, spinal puncture seemed to relieve or prevent convulsions The subjective symptoms were drowsiness, indifference, and sometimes irritability Eighty-five per cent had vomiting as an initial symptom This vomiting had no relation to the food taken, and in no case was there projectile vomiting as is so frequently seen in meningococcic meningitis Pain was a frequent symptom

In 18 per cent of the cases the urine showed acetone, and sometimes slight traces of albumin

Before death, pulse, temperature and respiration in about half of the cases became higher Early in the disease the pulse was slow and irregular, later in the disease it became soft and rapid In 64 per cent of the cases there was a remission, with a drop in pulse and temperature, but this was apparently not a sign of improvement Also, a patient, who may have been comatose, may brighten up and answer questions from twenty-four to thirty-six hours before death Forty-two per cent of the cases showed terminal bronchial pneumonia

In no case in this series was there recovery The treatment tried was sodium benzoate in large doses, and inunctions of mercury Hexamethylenamin was used in large doses, but even with these large doses there was never a trace of formaldehyd found in the spinal fluid This seems again to disprove the value of this drug in cerebrospinal inflammations

CEREBROSPINAL MENINGITIS

The treatment of meningococcus meningitis was thoroughly considered in THE JOURNAL, April 3, 1915, p 1158, and again on page 217 of "Prevention and Treatment of Infections"

The value of the Flexner serum continues to be shown, but it is not generally recognized that it often has curative value, even after the child has been sick with this disease for days and even weeks Smith[1] reports five cases all cured by meningococcus antitoxin, and four of these patients had been sick four days, nine days, twenty days and twenty-three days, respectively These five patients not only were cured, but they recovered without sequelae The history of these patients and the results show the value of repeated injections of the serum, and also the value of withdrawing the cerebrospinal fluid at frequent intervals, even after the fluid has become clear and there are no organisms to be found either microscopically or by culture

All nervous symptoms in these cases were ameliorated after lumbar puncture The fact that as much as 80 c c of fluid was withdrawn at once shows that normal absorption of fluid is interfered with, and that the removal of the surplus fluid is life-saving

Smith's finding bears out the clinical fact recognized before the discovery of the meningococcic serum that repeated spinal punctures and drainage in cerebrospinal meningitis frequently save life

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES"

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL

W A PUCKNER, SECRETARY

OUABAIN, CRYSTALLIZED (See N N R, 1915, p 103) —*The following non-proprietary preparation has been accepted*

G Strophanthin (Thoms) Merck—Manufactured by E Merck Darmstadt Germany (Merck and Co New York)

MERCURY BINIODIDE OIL SOLUTION IN AMPULES, H W & Co—One Cc of solution contains red mercuric iodide in a neutral fatty oil, 0 1 Gm. (1/6 grain) Each ampule contains more than 1 Cc

(Accepted for inclusion in the appendix to New and Nonofficial Remedies)

Prepared by Hynson, Westcott & Co Baltimore

MERCUROL (See N N R, 1915, p 197) —The following dosage forms have been accepted

Mercurol Tablets ¼ gr—Each tablet contains mercurol 0 016 gm (¼ grain) Prepared by Parke, Davis & Co, Detroit.

Mercurol Tablets ½ gr—Each tablet contains mercurol 0 03 gm (½ grain) Prepared by Parke, Davis & Co Detroit

Mercurol Tablets 1 gr—Each tablet contains mercurol 0 065 gm (1 grain) Prepared by Parke Davis & Co, Detroit

Mercurol Tablets 2 grs—Each tablet contains mercurol 0 13 gm (2 grains) Prepared by Parke Davis & Co Detroit

Mercurol with Potassium Iodide Tablets—Each tablet contains mercurol ¼ grain and potassium iodide 1 grain Prepared by Parke, Davis & Co Detroit

IODALBIN (See N N R., 1915, p 157) —The following dosage form has been accepted

Iodalbin and Mercurol Tablets—Each tablet contains iodalbin 5 grains and mercurol 1 grain. Prepared by Parke, Davis & Co Detroit

LIQUID PETROLATUM — Petrolatum Liquidum—Liquid petrolatum is described in the U S Pharmacopeia For description see the Pharmacopeia or Useful Drugs

Non-Proprietary Preparation

Liquid Petrolatum Merck —Liquid petrolatum made from American petroleum It is colorless, nonfluorescent practically odorless and tasteless. Specific gravity 0 855 at 15 C or 0 846 at 25 C. It complies with the tests of the U S Pharmacopeia (8th ed)

Merck & Co New York

SATURDAY, DECEMBER 25, 1915

On account of the large amount of space occupied by the Index in this issue of The Journal, certain departments have been omitted entirely and others abbreviated

THE INDEX AND HOW TO USE IT

This number of The Journal contains the index to Volume LXV, July-December, 1915 If this were all the index contained, comment would be unnecessary It is not, however, simply an index to the matter printed in The Journal, but covers also the articles that have appeared in the principal medical journals of the world—seventy-nine domestic and eighty-one foreign It is a practical everyday working index to current medical literature, cross indexed by subjects, authors, etc The preparation and issuing of such an inclusive index is a rather large undertaking Those who have any idea of what this work means will appreciate this the more when it is realized that the index in this issue occupies 320 columns Sometimes a doubt arises whether the index is fully appreciated by those who have occasion to look up bibliographic references So many letters are received requesting The Journal to supply references to literature when the writer has the index at hand, that it is feared sometimes that readers do not fully realize its value

To facilitate the use of the index it has been the custom to make a separate publication under the title, "Guide to Current Medical Literature" This includes, in addition to the index as it appears in this issue, the titles of articles arranged chronologically and by journals as they appear weekly in the Current Medical Literature department of The Journal[1]

The loan feature by which our readers, for the sum of 6 cents in postage, may borrow certain foreign journals listed in the index is being appreciated more and more, and evidently is proving of great convenience and usefulness to physicians There looms up the possibility that The Journal will be compelled to subscribe for extra copies of some of the more important foreign journals in order to supply the demand

RECENT ADVANCES IN KNOWLEDGE OF ALLERGIC PHENOMENA

An important step in the development of our knowledge of the phenomena of immunization was the demonstration that the treatment by injection of an animal with a foreign protein, bacterial or otherwise, leads to profound changes in the body which may endanger as well as protect the life of the animal when this protein is reinjected These changes are characterized by the formation of antibodies which, while they increase the resistance of the animal against subsequent inoculations of toxins and microbes, certainly seem to render the body highly susceptible to poisoning in the instance of innocuous proteins This apparent hypersusceptibility, which we speak of as allergy or anaphylaxis, may be so marked that a second injection of the foreign protein results in severe or even fatal injury to the animal The clinical and pathologic picture of the allergic reaction suggests that the injury to the cells is due to a poisonous action, and an early explanation of anaphylactic phenomena assumes that under certain conditions toxic substances are liberated as a result of a reaction in vivo between the protein and its antibody On such a hypothesis has been developed the widely accepted theory of parenteral digestion Vaughan, using chemical methods, found that all proteins contain a similar poisonous group which can be liberated when the protein molecule is broken up Furthermore, when this toxic product is introduced into an animal, a condition quite typical of anaphylactic shock results Hence he concluded that protein sensitization is due to the development of a specific proteolytic ferment in the body which acts on the reinjected protein and liberates the toxic element This supposition that a specific protease is formed when a foreign protein is introduced into the body has been developed also by Abderhalden and his associates By the use of biologic methods, Friedemann and Friedberger were able to demonstrate that poisonous products could be obtained, for example, by treating red blood cells or bacteria with fresh unheated guinea-pig's serum (complement), and they thought that the toxic substance in anaphylaxis is formed from the antigen, and that in this process, which Friedberger assumed to be intravascular, the complement plays an active rôle The fundamental hypothesis of the theory of parenteral digestion as developed by Vaughan, Friedemann, Friedberger and others has been generally accepted, but there is still much difference of opinion as to the matrix of the toxic fraction and the mechanism by which it is formed in the body

While the principle that allergic phenomena are due to enzymatic proteolysis has been upheld, much doubt has been cast on the early assumption that the antigen furnishes the toxic product Using insoluble substances such as agar, kaolin and barium sulphate instead of bacteria and red blood corpuscles, many observers found that these substances when treated with horse serum and then with guinea-pig serum yield a poison similar to the so-called anaphylatoxin of Friedberger Such experiments strongly indicate that the toxic product is formed by the action of the complement on the horse serum absorbed by these insoluble substances Again, the observations of Jobling and Petersen, recently reviewed in these columns,[1] emphasize the importance of the proteins of the animal itself as the matrix of the poison in the allergic reaction Jobling and Petersen find that bacteria as well as agar, kaolin and chloroform, when mixed with fresh guinea-pig serum, absorb the antienzymes normally in the blood and thereby render the serum toxic They assume that poisons are formed because the nonspecific proteolytic ferments of the blood are liberated through the absorption of the antienzymes by the antigen injected, and now the blood proteins undergo digestion Does the complement enter into these proteolytic changes? The experiments of Friedberger and others indicate that there is a diminution of the complement during protein intoxication, but there is no other evidence of a convincing nature to establish the assumption that it plays an active rôle in the proteolytic process

---

[1] See advertising page 2

As to the localization of the allergic mechanism, recent researches permit certain definite statements The earlier investigators, especially Friedberger, explained anaphylactic shock as entirely due to an intravascular mechanism, but later work points to the probability that cellular reactivity is of the greatest importance Pearce and Eisenbrey, using transfusion methods, and Schultz, Dale and Weil, using isolated muscle tissue of sensitized animals, have shown conclusively that the condition of hypersensitiveness is largely determined by an increased capacity for reaction on the part of the fixed cells to the specific antigen In other words, allergy is largely due to a changed reactivity of the cells, occasioned, we may assume, by an excess of specific antibodies or enzymes in the protoplasm Such a condition easily explains both the acute death in sensitized animals and also the local skin reactions that we ascribe to allergy But the experiments of Biedl and Kraus, Friedemann and others afford evidence that all the factors necessary for the production of allergic reactions may be present in the blood stream, hence, in the light of these two lines of evidence, it seems logical to conclude that both fixed cells and the blood stream are capable of furnishing the necessary agencies in the production of protein intoxication

Although there is a great mass of experimental data at hand pertaining to allergy and associated phenomena, the facts are not sufficient to warrant any very definite conclusions The injection of a foreign protein into the body really does not render the body any more sensitive than before to that protein, but increases the power of reaction whereby the substance is more easily broken up Furthermore, in this reaction changes take place of both a chemical and a biologic nature, a correlation of which is fundamental in the thorough understanding of the phenomena of anaphylaxis

The application of the knowledge of the allergic phenomena to the study of bacterial infection and immunity is difficult, for numerous factors enter into the reaction which are not present in the instance of unformed proteins Active sensitization of animals with bacterial proteins is not difficult to accomplish, however, and the treatment of bacteria in vitro with active serum results in the formation of acutely toxic products Doerr considers the bacterial cell as representing a group of antigens which, when liberated by lytic substances in the body, are free to act as unformed proteins Whether this explanation or that of Jobling and Petersen contains the solution of the problem, it still remains that whatever proteolysis takes place, toxic products may be liberated Thus in acute infectious diseases the invading bacteria stimulate the production of specific antibodies, which react with the bacteria, leading to the liberation of protein constituents of the bacterial cell On this basis the incubation time as well as the general reaction of the infectious diseases may be explained (von Pirquet) It is interesting to note that such an explanation would not be illogical in case of the acute eruptive diseases The possibility of the development of complete immunity against unformed, primarily harmless proteins seems questionable, for it has been demonstrated that animals with high antibody contents in their blood die following subsequent inoculations of the antigen But in the instance of cellular proteins, that is, microbes, a definite resistance is often developed which usually is characterized by a marked increase in the power of phagocytosis, a process the influence of which, if any, we are not able to trace in the reactions against unformed proteins

NEW FOOD GRAINS—PROSO AND KAOLIANG

We are accustomed to novelties in drugs Scarcely a week passes without the heralding of some new synthetic chemical compound, plant ingredient or animal tissue constituent to which therapeutic potency is attributed It requires not only a clear memory but also a critical judgment to cultivate a progressive and proper attitude of mind in the midst of such incessant therapeutic suggestions Far rarer are the proposed innovations in the domain of foods Now and then some unusual fruit or nut or green vegetable is brought to the attention of the public, but our "staple" crops persist unchanged in popular favor Corn, wheat, rye and potatoes each have a preferential place in dietary esteem in different localities, depending on tradition and geopraphic and economic conditions The praises of millet seed and sorghum grain as human foods have a truly novel ring, however, even in these days of possible shortage in the usual cereal food supply of some of the European countries

---

[1] The Antiferments of the Blood editorial, THE JOURNAL A. M. A Oct 30 1915 p. 1554

Millet, as is well known, has been cultivated for forage and grain since ancient times To Americans the name will at once suggest a fodder for animals, and its significance is not enhanced by the familiar designation of "hog millet" Professor Nansen[1] of the South Dakota Agricultural Experiment Station, who has investigated the possible use of millet as food for man, has suggested the substitution of "proso," the ancient Slav name for the grain The seed of proso millet, although practically unknown in America as a food for human consumption, is a familiar article of diet in Russia and India It is said that during the Russian famine of 1890 proso millet bread was for a long time the only food remaining between the peasantry and starvation The grain can be milled and cooked in the same ways as are many other cereals The composition of hulled proso is much like that of patent wheat flour, being even richer in protein The grain can be used whole, ground like corn meal and thus made into palatable dishes, or used as flour The lack of gluten makes it necessary to combine proso with wheat flour if it is to be converted into a good bread A "public" test of proso as a table cereal was made at the South Dakota State College of Agriculture early in the present year, so that it has already experienced an "official introduction" From the standpoint of practical agriculture proso deserves consideration because, like kafir corn, it represents a crop which can be produced in dry seasons or in arid regions where the attempts to raise the more popular cereals are often discouraging

Another plant product tested for its possible usefulness as a human nutrient is kaoliang, a drought-resistant grain sorghum long used in Africa, India and parts of Asia[2] This plant, once a tropical annual, also can by careful selection be extended as far north as Indian corn on this continent Specimens of hardy kaoliang from China reached America as early as 1866, but were discarded because they seemed of no value for sugar making, the only use to which the sorghum plant was put at that time This sorghum seed can be milled, and when mixed with gluten-yielding flours kaoliang contributes to the production of palatable baked products as does kafir flour which has lately been exploited as a human food[3]

Variety in diet is a physiologic desideratum, and changes in our food staples occasionally become a climatic, agricultural, or economic necessity Sometimes revolutions occur in the domain of popular nutrition The potato was introduced in this way We must at least be equipped with detailed information of the increasing dietary and culinary possibilities in this field

---

THE EFFECT ON THE OFFSPRING OF LEAD POISONING IN THE FATHER

In articles on industrial lead poisoning, it is usual to find the statement that this form of intoxication results in fetal death and in death of offspring soon after birth, not only when the mother is the victim of the poisoning, but also when the mother is normal but the father "leaded" As far as maternal lead poisoning is concerned, there seems to be abundant evidence that women who work in lead are far more likely to abort than are women in ordinary factory work Legge[1] abstracted from the reports of British factory inspectors for the year 1897 the following statistics concerning women lead workers Of 77 married women, 15 were sterile, among the 62 who became pregnant, 15 never bore a living child The stillbirths numbered 21, the miscarriages 90, 101 living children were born but 40 of them died, leaving 61 living children as the result of 212 pregnancies Another striking report comes also from the British factory inspection service Oliver[2] quotes Reid's figures as follows For 100 mothers engaged in housework, there were 43 2 miscarriages and stillbirths, for 100 mothers engaged in mill work, not lead, 47 6, for 100 mothers, in lead work before marriage, 86 0, for 100 mothers, in lead work after marriage, 133 5 Tardieu[3] reported to the French government in 1905 that 608 out of 1,000 pregnancies in lead workers resulted in abortion Animal experiments also, carried on by Oliver, by Gilbert, and by Legge and Goadby, show that death of the fetus may be produced by poisoning the mother with lead

In those countries in which many women are employed in the lead industries, these facts are of great importance and have resulted in laws forbidding the employment of female labor in certain processes In the United States, few women employees are exposed to lead poisoning, and we are more vitally interested in the question whether or not paternal plumbism has any effect on the germ The conscientious seeker after evidence will find far less to support the theory of paternal influence than of maternal, indeed, he will wonder at the positiveness on this subject shown by many textbooks on industrial diseases There is the report of Chyzer[4] which is often quoted, concerning degeneracy among the children of Hungarian potters But pottery dipping is a house industry in the Hungarian villages, and there is ample opportunity both for maternal poisoning and for poisoning of the children after birth A few statistics are furnished us from France Rudeaux[5] in 1905 stated that out of 442 pregnancies in women married to lead workers, 66 ended in abortion and 241 in premature birth The most often quoted report on this subject is Constantin Paul's,[6] written in 1860 Lewin[7] seems to have borrowed it in 1904 and republished Paul's figures without quotation marks, and as German medical literature is read more than French in this country, the figures are almost always attributed to Lewin They are as follows Seven wives of lead workers who had given evidence of plumbism had 32 pregnancies, of which 11 ended in abortion, and 1 in stillbirth Of the 20 children born living, 8 died in the first year, 4 in the second, 5 in the third and 1 after the third, leaving only 2 alive out of the 32 pregnancies

[4] Chyzer Chir Presse, Budapest, 1908, xliv, 906

This is, after all, slender evidence on which to base positive statements on so important a matter as the effect of paternal lead poisoning on the germ, and we are grateful for two experimental studies in this field which have just been published independently Cole and Bachhuber,[8] working at the Wisconsin Agricultural Station, fed lead acetate to rabbits and fowls Experiments with rabbits resulted in a mortality of young during the first four days after birth of 47 7 per cent for offspring of leaded males as contrasted with 29 2 for the offspring of normal males The average weight at birth was 49 8 grams for the former, 59 0 grams for the latter With Leghorn hens the results were similar When the hen was bred to a cock which had been fed lead acetate, 27 5 per cent of the embryos in fertile eggs died and 14 1 per cent of the chicks born alive died in less than three weeks, while the corresponding figures were only 17 2 per cent and 3 7 per cent when the cock was normal

C V Weller[9] of the University of Michigan used commercial white lead — basic carbonate — and fed it in capsules to guinea-pigs The experiments which interest us especially are those with leaded males, and these are some typical results which he obtained

	Free Female Mated with	
	Free Male	Lead Male
Number of offspring	58	65
Average birth weight, grams	81.5	66.3
Number stillborn	3	3
Died first week	2	9

The effect of alternate matings of the same normal female with a normal and with a lead male is also interesting For instance, the birth weights of the offspring of a free male were 79 gm in two instances, and of a lead male 54, 47 and 40 gm

The results of paternal lead poisoning in guinea-pigs are shown, not in sterility or in stillbirth, but in reduction of weight at birth, and this underweight persists through life Next to this the most striking change is the high rate of mortality during the first few days after birth Nine out of 65 offspring of leaded males died during the first week, but only two out of 105 offspring of control males

In a lecture on industrial plumbism delivered in London in 1911, Thomas Oliver declared that from the purely physical point of view a nation's strength is measured by its reproductive powers and the high percentage of fitness of its children He then went on to point out the danger to the race of industrial plumbism, especially as it affected potential mothers In our country this danger is largely confined to men, but that it is a serious evil in our lead trades has been shown by numerous state and federal investigations If we are to believe that this results in impairing the efficiency not only of this but also of the coming generation, it would make a strong argument for the legal regulation of the lead trades

PUTREFACTION PHENOLS AND PROTECTIVE MECHANISMS IN THE BODY

It has long been known that when urines are distilled with a mineral acid, phenols may be recovered in the distillate This result is obtained not only when phenol (carbolic acid) itself is absorbed through some channel into the circulation, but also under ordinary conditions of diet and health in which the antiseptic has never been employed Baumann showed that in the urine itself the phenols are present in the form of ethereal compounds Among these are the organic or "conjugated" sulphates and the glycuronic esters of the phenols The fact that in "carbolic acid urines" the phenol occurs in the form of an ethereal sulphate early became a classic example of the detoxicating power of the animal organism This was comparable with the protective reaction by which indol derivatives were found to be excreted as ethereal sulphates, particularly in the form of the clinically familiar indican of the urine

At first it was believed that the phenol derivatives in the urine owe their origin to plant products in the food for the urine of herbivora was observed to be particularly rich in its yield of the phenols The progress in the study of the chemistry of putrefaction presently developed a new interpretation In man the elimination of phenol was seen to be increased by a diet rich in proteins The latter yield tyrosin, which can be converted into phenol and cresol by putrefactive changes Here, then, was the key to the sequence of events Proteins, tyrosin, intestinal putrefactive changes with production of phenols and their alimentary absorption, condensation to phenol esters, and excretion in the urine — these were the steps Like indican, which owes its origin to the tryptophan complex of the proteins, the phenols likewise became an index, so to speak, of putrefactive conditions in the bowel By vigorous catharsis phenols are made to disappear from the excretions, whereas in severe constipation or intestinal obstruction they are reported to be increased in amount

In the light of all this interesting information it seemed at first to be merely a question of expediency as to which of the various excretory products of putrefaction should be measured to furnish a helpful clinical guide to intestinal conditions The indican tests, being easily applied, were earliest in use and still enjoy a widespread popularity When they are "checked up" by estimations of the ethereal sulphate in the urine it is frequently found that there is a lack of correspondence between the two Either other substances than indol compounds are eliminated as conjugated sulphates, or the indican precursor may find its way into the urine in a form other than sulphate Both circumstances are known to occur The phenols may add to the content of "ethereal" sulphate, and the indol derivatives may leave the body as glycuronates And when it comes to a practical application of the urinary content of either phenols, indican or ethereal sulphates to the question of the extent of the putrefactive conditions in the bowel, experience has shown that the diet as well as the bacterial invaders plays a dominant part If the food is deficient in protein precursors of these peculiar excretory products the latter are necessarily reduced in amount Without a suitable pabulum the putrefactive micro-organisms cannot manifest their characteristic reactions

In all of this development of our knowledge of the interrelations between putrefactive products and urinary derivatives, it has for the most part been tacitly assumed that the conversion of the harmful into the more harmless product is ordinarily quite complete Certain it is that the ethereal sulphates of the urine are decidedly increased after the deleterious compounds have been introduced into the organism Considerable interest will be awakened, therefore, by the recent communication of Folin and Denis[1] demonstrating that the phenols are by no means quantitatively converted into conjugated phenols in the body This fact has been established by the use of an improved method of analysis[2] The free phenols, of which the most important quantitatively is doubtless paracresol, represent from 30 to 90 per cent of the total output In addition to this unexpected finding, the excretion of total phenol products in the urine appears to be much greater than is indicated by the phenol figures heretofore recorded in the literature The new data furnished by Folin and Denis indicate 0 3 to 0 5 gram of "total phenols" in a twenty-four-hour quantity of human urine Normal human subjects (as well as larger animals) yield comparable figures, and those furnished by infants and children are proportionate In some children there is little or absolutely no conjugation, the whole of the phenols being excreted in the free form As the Boston investigators remark, this is unexpected when considered from the prevailing concept of the protective mechanism by means of which the phenols are supposed to be detoxicated through transformation into conjugated compounds The phenol excretion tends on the whole to be much higher on protein-rich diets and lower on a regimen containing smaller amounts of protein

The possible bearing of these newer discoveries on current conceptions of the pathology of nutrition is intimated by Folin and Denis In general, they state, biologists are inclined to assume that the protective processes are adequate — that certain poisonous or deleterious substances are easily converted into harmless compounds, while the clinicians are constantly considering established or possible deficiencies and generally believe in "auto-intoxications" as an important feature in the etiology of diseases The inadequacy of some of these supposedly perfect protective mechanisms hitherto championed by the physiologists has been brought to light in the case of the phenols

THE LIVER AND FAT METABOLISM

A considerable number of diseases either border on or are actually classified as attended with an infiltration of fat in some of the organs The abnormal states of the body in which an infiltration of the liver, for example, has been observed include such diverse and unlike cases as diabetes, poisoning with phosphorus, phlorizin, chloroform or alcohol, emaciation, pernicious diarrhea, etc A symptom which is common to such a variety of pathologic conditions cannot well represent the fundamental etiologic factor in each instance, on the contrary, it is far more likely that the common feature is the outcome of, or is conditioned by, some primary disturbing agency As one of the authorities in this field says, the common factor of the above-named pathologic conditions "is undoubtedly a disturbed or deficient metabolism either of protein or of carbohydrate" In all these cases the fat reserves must be mobilized to supply material for the energy changes ordinarily furnished by the other foodstuffs

Why the liver should be singled out so conspicuously for this "mobilization" of fat has long remained obscure More recent comparisons of the fats ordinarily present in the hepatic tissue with those found in the usual fat-storage localities of the adipose tissue have furnished the clue to a possible explanation The fat from the fat depots like the subcutaneous tissue, the omentum, mesentery, and adipose tissue about the kidney consists essentially of the glycerids of fatty acids, such as palmitic, stearic and oleic acids Of these the oleic acid is an "unsaturated" organic compound Without elaborating the chemical details it may suffice to say that the content of unsaturated fatty acids in any fat is indicated by the amount of iodin it can absorb The "iodin values" of the fats therefore have a useful significance in this respect It appears that under ordinary circumstances the fats of the liver, heart and kidney have much higher iodin values than the fats which are deposited in the fat depots of the body and are derived directly from the food fat as well as by synthesis from other absorbed nutrients

---

[1] Folin, O, and Denis, W The Excretion of Free and Conjugated Phenols and Phenol Derivatives, Jour Biol Chem, 1915 xxii 309

[2] Folin, O, and Denis, W A Colorimetric Method for the Determination of Phenols (and Phenol Derivatives) in Urine, Jour Biol Chem, 1915, xxii, 305

The unsaturated fatty acids are apparently more readily oxidizable than the normal compounds Leathes[1] has expressed the view that the liver exercises the function of "desaturating" fats brought to it so that they are prepared for the subsequent metabolic processes "It looks," he fancifully remarks, "as if the work of the liver consisted in an operation which may be compared to the drying of gunpowder The fats we take in our food are remarkably unreactive substances, and it has always been one of the most astonishing chemical achievements of animal cells that they should be able to burn up completely and cleanly as they do so stable a structure as saturated fatty acids like palmitic or stearic acids They are wet gunpowder And the body stores its gunpowder wet, and safely removed from the inflammatory operations of busily working cells When the orders for mobilization are issued this wet powder is conveyed to the drying chambers in the liver, and from there distributed to the fighting line in a proper condition for use There are times when the stress of this work is manifestly too great Too active a mobilization of stored fat, or too little activity in dealing with it on the part of the liver, will result in an accumulation of the unfinished product in that organ A fatty liver is then the result, and the fatty acids which it contains are found to have a low iodin value There is an accumulation of wet powder"

In harmony with the foregoing, Mottram[2] has recently pointed out that, in the case of infiltration, the fat is in the liver for physiologic, not pathologic, reasons When there is need for fat for energy transformations, particularly when the other foodstuffs such as sugar are not available for nutritive purposes, the liver is found to be infiltrated with fats, presumably in order to be chemically transformed in some degree before they are handed on for use elsewhere It is interesting to recall that absorbed food fat is not carried directly to the liver as the other digestion products are, but it enters the circulation directly by way of the thoracic duct and thus avoids the hepatic cells before it is carried to the storage places for fat Mottram suggests that when energy is wanted by the body in a nutritive emergency as the result of some pathologic condition, it might be advantageous to save the liver the work of desaturation by feeding fats containing a high percentage of unsaturated fatty acids These are found in some of the fish oils like cod liver oil, and in such food products as sardines and herring Opie and Alford[3] have noted that ordinary fat is not an advisable food in conditions like chloroform poisoning, in which infiltration ordinarily occurs in notable degree

The view which presents infiltration of the liver as a physiologic response rather than a pathologic consequence is supported in an indirect way by the usual absence of degenerative histologic features in this organ It explains the fatty infiltration of the liver observed during late pregnancy and early lactation[4] Evidently the fetus is greedy for unsaturated fats, which are worked up for its benefit by the liver

It is generally accepted that acidosis, in the sense of ketonuria, is related in the body to the fats as its antecedent Ketonuria occurs under the same conditions that manifest fatty infiltrations of the liver When the isolated liver is perfused with fatty acids the acetone substances may arise Mottram[2] postulates that just as the infiltration is an expression of a physiologic function (desaturation) in fat metabolism, acidosis leading to ketonuria is the result of the fatty acid pursuing an abnormal path of metabolism, possibly as a result of overwork of the liver Either condition is relieved when carbohydrate is available Whether the usefulness of unsaturated oils is likewise indicated, as has been suggested, remains to be ascertained

Current Comment

THE BILE AND CHOLESTEROL EXCRETION

There appears to be little doubt at present that cholesterol (or, as it is sometimes designated, cholesterin) can be absorbed in the alimentary tract from such food intake as may contain it This has been ascertained in particular from the fact that after suitable feeding of foods rich in cholesterol, the content of this substance in the blood may be increased Cholesterol is found, among various tissues and fluids of the organism, in the bile The origin of the biliary cholesterol, which betrays itself in a familiar pathologic way in the formation of gallstones, is by no means certain as yet It may be derived from disintegrating red blood cells, or it may represent food cholesterol that is being eliminated in the only excretory fluid that contains a suitable solvent for it Whether the bile presents a normal or physiologic mode of excretion for cholesterol has been much debated In so far as the evidence on this subject is derived from an examination of bladder or fistula bile, it must be remembered that the cholesterol thus found may have its origin in the walls of the biliary passages Naunyn always defended the view that this is the case Inasmuch as bile from the gallbladder is much richer in cholesterol than that from a fistula it was contended that this substance is added to the bile largely by the epithelium of the bladder The evidence is, however, by no means conclusive A number of feeding experiments have been undertaken by various investigators at different times to ascertain whether an abundance of cholesterol in the diet would be attended with an increase of the substance in the bile The results, from which it was hoped to learn whether absorbed cholesterol would be excreted again in the bile, have been rather conflicting or indecisive In the newest experiments conducted by D'Amato[1] at the University Medical Clinic in Naples, on dogs with biliary fistulas, it appears that a diet rich in food containing cholesterol does increase the content of cholesterol in the bile But the increment is so slight and insignificant in comparison with the quantity of cholesterol fed that there is no real justification for the contention that the bile forms a prominent mode of excretion for the substance under discussion Furthermore, there is no convincing evidence that cholesterol is converted, as some have assumed,[2] into cholic acid, which enters so largely into the make-up of the bile salts

OSTEITIS DEFORMANS

Any disease which can claim a record of scarcely more than 200 authenticated cases in the modern literature of clinical medicine surely deserves to be classed among the rarer maladies This situation applies to osteitis deformans, which Sir James Paget, who described it in 1876, termed a "rare disease of bones" Although in its advanced stages it presents an unmistakable clinical appearance, there have been comparatively few scientific investigations of osteitis deformans Heredity, syphilis and other bacterial infections have at times been regarded as predisposing causes, but there is little to justify this belief in the light of more critical analysis of the case reports and laboratory findings Neurotrophic factors have seemed to some students of the disease to be more likely causes of the bone dystrophy, perhaps because so little that is definite can be postulated in relation to the association of bone defects and nervous disorder An opportunity to make a study of new cases of osteitis deformans has arisen at the Jefferson Hospital in Philadelphia The unusual feature of the investigation there[3] is the detailed examination of the metabolism in two cases, one advanced and the other early In the advanced case there was a pronounced retention of calcium, magnesium and phosphorus This metabolic picture is thus to a certain degree the reverse of that seen in osteomalacia In the latter disease, the skeletal structures of the organism have been depleted through the resorption of both organic and inorganic substances Inasmuch as calcium is the principal element concerned in bone growth, the significance of the observed high retention of this element in osteitis deformans may be related to the abnormal development of certain portions of the skeleton It must be stated frankly, however, that some students of the disease assert that the increased development of the bone or bonelike structure is not accompanied by the calcification of these parts, though the few available analyses tend to support the evidence of positive calcification The association of acromegaly and gigantism with disease of the pituitary gland, and likewise the osseous lesions of cretinism in which the thyroid is unquestionably concerned, have justified the Philadelphia investigators in a hypothesis in regard to osteitis deformans They recall that the interrelation of disorders of the bone metabolism and perverted function of some of the ductless glands has been verified in certain cases This fact, together with other observed features of abnormal calcium metabolism, leads them to the belief that Paget's disease also is a disorder of bone metabolism probably dependent on the absence or perversion of some internal secretion Every available opportunity in the future ought to be utilized to consider the etiology of osteitis deformans critically in the light of the suggestions here recorded

THE KIDNEYS AS A FACTOR OF SAFETY

"For a score of years, or more, in many of us the kidney is gradually losing some of its valuable material from one cause or another without any symptom, without a reminder sufficient to spoil our pleasure of life or to hamper our activities Not until that luxurious surplus is approaching its exhaustion do we get a warning But then our work is mostly done and our time limit nearly reached" This quotation, from a lecture by Meltzer[1] on the factors of safety in animal structure and economy, may serve to remind us not only that we are continually producing metabolic products which would be harmful if they were not promptly removed from the body, but also that our organism is doubtless absorbing substances from the varied intake of food mixtures which might be expected now and then to exhibit toxic effects, were it not for the efficiency of the excretory organs In other words, it is not at all improbable that we frequently escape the detrimental possibility of ingested products because they are excreted so promptly and completely that they cannot accumulate in sufficient concentration to do harm in the body The actual danger never reveals itself unless the eliminating organs have had their potency impaired in some way An interesting illustration has recently been furnished by Smillie,[2] who has found that a potassium salt such as the chlorid, in a dose which is harmless to normal individuals may be injurious in nephritis Inasmuch as suitable patients may react to potassium chlorid without showing adverse effects from comparable quantities of sodium chlorid, the "salt action" cannot account for the effect It may be assumed, therefore in the constant presence of the chlorin ion, that the toxicity is due to the potassium ion Smillie has found that rabbits die with great suddenness after an ingestion of 1 gm (15 grains) of potassium chlorid, if they have acquired an experimental uranium nephritis of a degree sufficient to increase the nonprotein blood nitrogen to 100 mg per hundred cubic centimeters The fatal outcome is not due to "salt action" but probably to the action of the potassium ion on the heart muscle Comparable acute poisoning was also observed in human nephritis This acute intoxication occurs probably because the salt, which normally is readily absorbed and very rapidly excreted, in nephritis is readily absorbed but not excreted, thus reaching a concentration in the blood which is injurious Such a demonstration is highly significant in its relation to the management of diet in nephritis Some of our foods, notably the vegetables, are particularly rich in potassium Smillie refers to a calculation indicating that a man who took a large part of his food in the form of potatoes might have an intake of ten times the fatal dose, calculated on the basis of experience on animals with kidneys removed Bunge has actually reported taking more than half an ounce of potassium salts in a day Were it not, says Smillie for the fact that potassium salts are so rapidly excreted by the kidneys in health, the effects might be very serious

COOPERATION IN INDUSTRIAL HEALTH INSURANCE LEGISLATION

At the request of the American Association for Labor Legislation, the Council on Health and Public Instruction of the American Medical Association has appointed a committee to assist in drafting a health insurance bill to be introduced into the legislatures in session in 1916 The committee consists of Dr Alexander Lambert of New York, chairman, Dr Henry B Favill of Chicago, and Dr Frederic J Cotton of Boston The preparation of this bill and the plans for its immediate introduction into several legislatures have removed health insurance from the realm of academic discussion and have placed it in the front rank of the pressing practical questions confronting the medical profession The Association for Labor Legislation, which is responsible for this bill, has been influential in securing the enactment of workmen's compensation laws in thirty-three states within five years It has also worked for protection against industrial disease, and drafted the federal law abolishing the use of poisonous phosphorus in matches In its legislative program it has been backed by progressive employers, by representative labor leaders and by members of the medical profession interested in industrial diseases Every extension of its activities in the field of industrial hygiene has made increasingly clear the absolute necessity for making systematic provision for sickness of working men, which is possible only through a comprehensive system of health insurance In preparing its bill, which is the next step in health legislation the association wisely has recognized that adequate medical care is of the first importance, both to the wage earner and to his family, and it has been equally wise in asking the cooperation of medical men in drafting those provisions which affect physicians The certainty that such laws will be enacted within a few years, the success of the American Association for Labor Legislation in obtaining the legislation it advocates, and the consideration shown to the medical profession have convinced the Council on Health and Public Instruction that cooperation is desirable and opportune This close cooperation will guarantee that the best interests of the medical profession under health insurance will be borne in mind at every step

THE INCORPORATION OF THE AMERICAN MEDICAL ASSOCIATION

On last Monday, December 20 the Supreme Court of Illinois rendered a ruling — it was not a decision as the newspapers stated, but simply a ruling — in the case of *Lydston vs the State's Attorney* The newspapers, in sweeping statements — inspired? — have carried the impression that the ruling is against the American Medical Association, that the officers, including trustees, are holding their offices illegally, that a new election must be held immediately, etc Nothing could be farther from the truth It is the old story, it is merely another step in the case started about the time of the meeting of the American Medical Association in St Louis in 1910, at which time Lydston tried to compel the state's attorney to bring quo warranto proceedings against the Association The American Medical Association has not yet technically been brought into the case, thus far the issue has been between Lydston and the state's attorney The technical announcement of the ruling just made is "*Hoyne, State's Attorney,* vs *People ex rel,* Lydston, petition certiorari denied" The state's attorney tried to get a decision from the Supreme Court, but the Supreme Court declined to hear the case at this time and therefore denied the writ of certiorari

Foreign Technic—In technic the general observation is made that the foreign operator does much more of his own work than is the rule with us He assists himself notably He often ties, cuts and sponges himself Yet he obtains no small speed His assistants are usually far better trained than ours because they work longer with him Man or nurse, the same individual has learned to know, by years of association just what the next need or move of the surgeon is to be, and the assistant, even when changed as in Britain, does not stay less than six months, and is a senior on salary The operator may even thread his own needles and lay out his own simplified outfit Lessened infection is said to result from a minimum number of persons in contact with instruments sponges and wound—Robert L Dickinson

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest, such as relate to society activities, new hospitals, education, public health, etc)

CALIFORNIA

Municipal Clinic—A municipal clinic for the treatment of tuberculosis in Sacramento is practically assured A site has been secured at Second and Q Streets, and the clinic will be opened early in the year

Physician Wins Malpractice Suit—In Judge Woods' court, November 12, a jury rendered judgment in favor of Dr James C Negley, Los Angeles, in the suit for $30,000 brought against him by Agatha Wells for alleged malpractice

Hewlett to Succeed Wilbur—Dr Albion Walter Hewlett, formerly professor of internal medicine at the University of Michigan, Ann Arbor, was appointed, December 8, to succeed Dr Ray Lyman Wilbur, president-elect of the University of California, as professor of medicine at Stanford University

Hookworm—The California State Board of Health will establish headquarters in Los Angeles for the study of hookworm disease which is said to afflict many of the miners in Southern California The malarial belt of the Sacramento Valley will also be studied Dr James G Cumming, formerly head of the Pasteur laboratory at the University of Michigan, Ann Arbor, has been appointed head of the laboratories in Los Angeles

Head of Tuberculosis Bureau—Miss Edythe L M Tate, executive secretary of the California Association for the Prevention of Tuberculosis, has won first place in a competitive examination held by the California Civil Service Commission for a position as director of the Tuberculosis Bureau of the State Board of Health, which carries with it a salary of $3,000 Miss Tate was largely instrumental in securing the passage of the law appropriating $75,000 to the Tuberculosis Bureau

Personal.—Dr Frederick Parker Gay, professor of pathology in the University of California, Berkeley, has been selected as faculty research lecturer for 1916 and will give the annual public address on the result of his own research in some special field at the University of California, March 23, 1916 Dr Gay's selection was in recognition of his recent work in developing improved methods for the treatment of pneumonia and typhoid fever——Dr Norman Bridge, president of Throop Institute, Los Angeles, was the guest of honor at a dinner given by the Chicago members of the Alumni of Lake Forest College and representatives of the faculty of that institution at the University Club, Chicago, December 9——Lillian J Martin, professor of psychology at Stanford University, has been appointed head of the department of psychology, succeeding Dr Frank Angel, who has resigned to take charge of the Belgian relief work in London and who sailed for the war zone, December 10——Dr Charles C Landis, Chico, will leave for China next month He will be located in the province of Hunan as a missionary of the Adventist Church——Dr Thomas A. Stoddard, Santa Barbara, has returned after several months' work in a British base orthopedic hospital, Liverpool——Dr Percy T Phillips, Santa Cruz, has been appointed a member of the State Board of Medical Examiners, succeeding Dr Frederick F Gundrum, Sacramento, who resigned to accept appointment as a member of the State Board of Health——Dr Ray Lyman Wilbur, dean of the medical department of Stanford University, San Francisco, will assume office as president of the Leland Stanford Jr University, January 1——Dr Josiah Morris Slemons, of the faculty of the University of California, has resigned to accept a similar position in Yale Medical School

DISTRICT OF COLUMBIA

Diphtheria—For the first ten months of 1915 there were 191 cases of diphtheria in Washington, with eleven deaths During the same period of 1914, 100 cases were recorded

Mental Hygienists Meet.—At the first meeting of the board of directors of the Society for Mental Hygiene of the District of Columbia, December 2, Surg-Gen Rupert Blue, U S P H S, was elected president, Mr Cuneo H Rudolph, first vice president, Dr D Percy Hickling, secretary, and Miss Nellie Sedgley, treasurer

Personal—Dr D Percy Hickling has been appointed chairman of the Public Health Committee of the Washington Board of Trade——Dr Edgar D Thompson has been selected as president of the North Capitol and Echington Citizens' Association——Dr Philip Newton is reported to have been made corps surgeon in the Russian service

District Society Election—At the annual meeting of the Medical Society of the District of Columbia, December 1, the following officers were elected president, Dr Edward Y Davidson, vice presidents, Drs Joseph D Rogers and Isaac S Stone, recording secretary, Dr Henry C MacAtee, corresponding secretary, Dr Arthur L Hunt, and treasurer, Dr Charles W Franzoni, all of Washington

Medal of Honor to Major Heller—A bill has been introduced into the senate to authorize the secretary of war to award the congressional medal of honor to Maj Joseph M Heller, M C, U S V, for unusual, distinguished and gallant action in attending the wounded under fire while a contract surgeon, U S Army, at the battle of Naguilan, North Luzon, Philippine Islands, Dec 17, 1899, and during the months of September, October, November and December of the same year while attached to the first battalion, Twenty-Fourth United States Infantry, First Division, Eighth Army Corps, under the command of Maj Gen H W Lawton, U S V

FLORIDA

Personal—Dr Grace Whitford, Ozona, has been appointed acting chairman of the health department of the Florida Federation——Dr Theodore G Croft has been appointed city physician of Jacksonville

New Officers—Duval County Medical Society at Jacksonville, December 7 president, Dr James H Pittman, vice president, Dr W Williams McDonell, and secretary-treasurer, Dr Herbert O Black, all of Jacksonville——Hillsboro County Medical Society at Tampa, December 7 president, Dr Louis S Oppenheimer, Tampa, vice president, Dr John W Alsobrook, Plant City, secretary, Dr Earle H McRae, Tampa, and treasurer, Dr William C Douglass, Tampa——Pinellas County Medical Association at Clearwater, November 11 president, Dr Franklin W Wilcox, vice president, Dr Alvin J Wood, secretary-treasurer, Dr William McK Davis, all of St Petersburg

GEORGIA

Personal.—Dr Howard J Williams has retired after twenty years' service as a member and president of the Macon Board of Health At the last meeting which Dr Williams attended, he was presented with a loving cup by members of the board—Dr Alfred F White, Flovilla, has been appointed a member of the State Board of Medical Examiners, to succeed himself——Dr Olin H Weaver has been appointed chairman of the Macon Board of Health

ILLINOIS

Personal.—Dr William E Range, Glen Carbon, has been obliged to go to the Southwest on account of the health of his wife——Dr and Mrs J L Huntington, Princeton, have decided to locate in Santa Barbara, Calif

Quarantine Lifted—Three counties of Illinois have been freed from quarantine for the foot and mouth disease and the quarantine in six other counties has been modified by an order from the Department of Agriculture, effective December 18 This order releases from quarantine the counties of Dupage, Livingston, Marshall and all of Cook County, excepting the Union Stock Yards, which remains a restricted area for handling animals for immediate slaughter

Chicago

Inspecting the Children—The health commissioner suggests that to supplement the efforts to improve the public health by inspection of the schoolchildren, the thousands of children gathered in the Sunday schools, particularly during the holiday season, should likewise be inspected He suggests that the pastors of the churches throughout the city and the superintendents of Sunday schools invite local physicians to look over the Sunday school classes on Sunday mornings or afternoons to determine whether any of them suffer from communicable diseases He believes that physicians would be glad to render this service without pay

Memorial Service for Dr Black—A memorial service for the late Dr Green Vardiman Black, dean of the Northwestern University Dental School, who died August 31, was held in the Hotel LaSalle, December 11, by the Chicago Dental Society Addresses were made by President Harris of Northwestern University, who spoke of Dr Black as the dean of the dental department of that institution, Dr Fred B Noyes, who paid tribute to the student, investigator and inventor, Dr C. N Johnson, who spoke on 'The Teacher and Writer", and Dr Thomas L. Gilmer, the subject of whose address was "The Man and Friend"

INDIANA

Trachoma.—Fifty cases of trachoma have been found in Indianapolis, some of the cases among schoolchildren

Personal.—Dr Clarence H Mead, health commissioner of Bluffton, is ill with diphtheria.——Dr Andrew J Gray Young America, is reported to be seriously ill as the result of a cerebral hemorrhage——Dr T Roy Cook, Bloomfield, who has been ill with general neuritis, is reported to be improving

Physicians Running Drug Stores—In one of the justice's courts in Indianapolis a physician was convicted of running a drug store without a license, because he had filled the prescriptions of another physician This case was appealed from the justice's court to the county criminal court where the verdict was upheld

Measles—Under date of December 18 it was said there were 140 cases of measles in Indiana Harbor A meeting of the health board with school physicians and inspectors was held to consider the epidemic A circular was prepared by the health department giving instructions to the heads of families with regard to the prevention of the spread of the disease.

MONTANA

Personal.—Dr Clem C. Seerley Manhattan is taking postgraduate work in New York City——Dr Alfred N Smith, Glasgow, has been appointed physician of Valley County——Dr Daniel J Donohue Glendive, has moved to Butte

New Society Organized.—The organization of the Southeast Montana Medical Society was perfected at Miles City December 3 Dr Wimon W Andrus, Miles City was elected president, Dr Virgil P Garst, Terry, vice president, Dr John G Randall, Missoula, secretary, and Dr Sadie B Lindeberg, treasurer, Miles City

NEW YORK

Emergency Health Expenditures.—The attorney-general in an opinion rendered to the health officer of the port of New York says that he may, with the approval of the governor not only expend the fees collected by him, but may employ any additional measures he deems necessary It is stated in section 37 of the state finance law that the health officer must turn into the state treasury by the fifth of each month the fees received by him This gives him in cases of immediate danger the power to use them in the protection of the public health

Tuberculosis Patients and the Law—The state law gives health departments power to enforce their mandates with reference to the care of tuberculous persons Many afflicted with tuberculosis are not careful to comply with the measures necessary to prevent the spread of the disease to others It has been necessary in some instances to enforce the regulations of health boards in this respect by application to the courts Several such instances have occurred in Buffalo Tuberculous persons who are refractory in this respect may even be sent to the penitentiary where special quarters are set aside for them

Health Centers—Buffalo has three health centers, the last established at the Municipal Hospital 770 East Ferry Street The two centers first established were very successful in their work This led to the opening of a third center and others may possibly follow The outstanding feature of the work at these centers is their cooperation with the various private welfare agencies The scope of these health centers includes prenatal work, child welfare—not only immediately after birth but until school age—supervision of midwives, prevention of blindness and conservation of vision milk dispensaries egg dispensaries, dental dispensaries tuberculosis dispensaries and social service This cooperation prevents waste of energy and the duplication of work, it will also save expense

New York City

Eminent Chemist Dead—A telegram has just been received announcing the death in New York City, on December 20, of Dr Rudolph August Witthaus, aged 69, the eminent chemist and toxicologist, professor of chemistry and toxicology in the University Medical College, New York City, and Cornell University, and emeritus professor since 1911, the author of several standard works on chemistry, urinalysis and toxicology

Building Fund for Women's Medical College—At the meeting of the Woman's Guild of the New York Medical College and Hospital for Women it was announced that $25 000 has been pledged toward the $200,000 required for a new building for the college The largest gift, $10,000, came from W W Cole, and Cornelia C. Brant, the dean of the college, gave $2,000 Among the subscribers are 104 women and 99 men

NORTH DAKOTA

Obtains Position in Red Cross.—Dr Thomas J Strong Williston, has received appointment as Red Cross director with the American Red Cross in Germany

State Laboratory Charges Fees—Dr Leverett D Bristol University director of the State Public Health Laboratory announces that the State Board of Regents has authorized the charging of fees for all work which is not strictly public health work and which the laboratory is not called on to do by the law

Health Survey of State—Surg Carroll Fox U S P H S, has completed his health survey of North Dakota and states in his preliminary report that the chief needs of North Dakota are a sanitary engineer who will devote his whole time to the work and whole-time health officers and correlation in public health service

Smallpox—At Grand Forks, December 2, it is said there were thirty-six cases of smallpox The vaccination order had been generally obeyed by the schoolchildren Attorney-General Linde has given an opinion that the regulations requiring vaccination may be enforced, although this is contrary to an opinion delivered by his predecessor There were also many cases in East Grand Forks The disease was mild and no deaths had occurred The health board by resolution urged on the board of education that a rule requiring the vaccination of all schoolchildren be established——In an effort to suppress an epidemic of smallpox at Bismarck the school authorities have prohibited teachers to attend theaters and children to attend motion-picture shows and have made vaccination compulsory——The physicians of Mandan are at hard work in an effort to prevent the spread of the disease

Hospital Notes—The new hospital at Fort Yates, Standing Rock Reservation, which has been erected at a cost of $26 000 is practically completed and will be opened early in January——A site has been selected for the Crosby Hospital on the Herring farm adjoining the city The building is to be 50 by 70 and two stories in height.——C C Marson, Cooperstown has agreed to donate a half block within the city limits providing a hospital is built thereon, and a quiet campaign is being carried on to secure funds for the construction of the building

OHIO

Health Sunday—Health Sunday was observed in Youngstown November 28, when the pastors of twenty churches gave up their pulpits to physicians who delivered addresses on various phases of public health

Conserving Vision.—Cincinnati is about ready to form its third class in the schools for the conservation of vision During the previous two years 3,475 schoolchildren with defective vision were found, 1,179 or 51 per cent., of whom were provided with glasses up to June 20, 1915 Regulations for the admission of children to the special classes have been published

New Faculty Appointments—The following appointments have recently been made to the faculty of Western Reserve Medical School Dr Julius M Rogoff of Vanderbilt University Nashville, Tenn., instructor of experimental medicine, Dr Cyrus H Fiske, Harvard Medical School, Boston, associate in biochemistry, Dr Roy W Scott formerly demonstrator in medicine in Western Reserve University instructor in physiology

Vaccination.—Notices have been posted at the mills of the Carnegie Steel Company at Youngstown requesting all employees to submit to vaccination in accordance with the recommendation of the Youngstown Board of Health The company will not compel the employees to be vaccinated, but they are strongly urged to submit to this measure, which will be carried out free of charge The Youngstown Iron and Steel Company had previously made a similar request of the men, and it is believed that all other industrial concerns in the city will follow this plan

Personal.—Dr Frederick E Dilley, instructor in surgery in the Union Medical College, Peking, Chih-li, China, has returned and will take postgraduate instruction in Cleveland until next August——Dr Alfred Irving Ludlow, professor of surgery and surgical pathology in the Seoul Medical College, Korea, will sail for the Orient, June 8——Dr George Niel Stewart, director of the H K Cushing Laboratory of Experimental Medicine at Western Reserve University, Cleveland, has returned from abroad——Dr Herbert E Twitchell, Hamilton, has been appointed assistant surgeon at the National Military Home, Dayton——Dr Eli R Crew, superintendent of the Miami Valley Hospital, Dayton, is ill and under treatment in the hospital——Dr Fred B Larimore, New Philadelphia, is seriously ill in the Columbus Hospital as the result of a hemorrhage

Cincinnati

Scholarship Donated—Gifts of $600 each have been made by Henry Strauss, Casper H Rowe, Adam A Kramer and Albert Lackman for scholarships in the medical department of the Cincinnati University

Return After Tour of Medical Colleges—Dr Christian R Holmes and Profs Martin H Fischer and H M Knower of the University of Cincinnati and Architect Harvey Hanford have returned after two weeks' tour of inspection of medical colleges in the East, and during which they submitted plans for the new medical college to experts for their consideration and criticism

Personal—Dr Samuel J Holdberg has been appointed assistant clinical instructor of laryngology and otology in the medical department of the university——Dr Lewis Bader has resigned as receiving physician at the General Hospital and will take up Roentgen-ray work He has been succeeded by Dr Max Shaweker——Dr Earl A Martin, Mount Vernon, has been appointed assistant to Dr Harry Freudenberger of the Tuberculosis Sanatorium——Dr Eric A Fennel has resigned as physician in charge of the City Infirmary and the two house of refuge farms

OKLAHOMA

Free Antitoxin—Dr John W Duke, Guthrie, state health commissioner, announced that free diphtheria antitoxin will be distributed in all deserving cases

Research Department to Be Established—Announcement was made, December 1, by the officials of St Anthony's Hospital, Oklahoma, of the immediate establishment of a medical research laboratory to be in charge of Dr Abraham Sophian, New York City, and of the building of an addition to the hospital to cost $150,000

Personal.—Dr I H Lamar, Texhoma, who has been ill with typhoid fever in Kansas City, has recovered and returned home——Dr Albert M Chambers, McCurtain, was recently operated on for appendicitis——Dr Benjamin W Ralston, Lindsay, is convalescent after a severe attack of septicemia——Drs Ross D Long and George D McLean, Oklahoma City, are on duty with the Allies in France

New Organizations—The Tulsa Academy of Medicine was organized October 28, and the following officers were elected president, Dr W Forest Dutton, vice-president, Dr Robert S Wagner, and secretary-treasurer, Dr Paul N Atkins——Physicians in the Henryetta District organized the Henryetta Hospital Association, November 27, electing Dr Nathaniel N Simpson, president, and Dr C N Stevenson, secretary-treasurer The purpose is to found and build a modern hospital A favorable report was made at this meeting on the plans and finances

PENNSYLVANIA

Personal.—Dr Joseph D Findley has been selected as health physician of Altoona, succeeding Dr Jesse P Seedenburg, removed from the city——Dr Frank Horning, Hellam, is reported to be ill at his home

Addition to Sanatorium—The Philadelphia Sanatorium for Consumptives at Eagleville is installing a completely equipped Roentgen-ray department for scientific study and research in pulmonary tuberculosis Dr Gilbert M Neuberger has been appointed roentgenologist

Philadelphia

Mütter Lecture Postponed—Owing to illness in the family of Dr Rudolph Matas, New Orleans, the Mütter lecture and reception scheduled for December 17 was postponed

Physicians Motor Club House—Negotiations have been completed for a club house and supply station for the Physicians' Motor Club of Philadelphia This will be ready for occupancy and transaction of business very soon after Christmas

Personal—Dr Charles B Penrose, who was taken suddenly ill with pleurisy in Baltimore and removed to Johns Hopkins Hospital, has greatly improved and will return to his home in a few days——Dr Mary W Griscom, who recently returned from a trip through the Far East, visiting medical women in isolated stations, was the guest of honor at a dinner given December 16, at the Hotel Adelphia, by a number of her associates——Dr Frank W Swallow has been appointed assistant medical inspector in the bureau of health——Dr William Hewson has been appointed an assistant school medical inspector——Dr Wilmer Krusen, the new director of health and charities, was the guest of honor at a dinner given at the home of Dr Frank C Hammond, December 9

Duhring Annex Dedicated—The Duhring Memorial Building recently erected annex to the library of the University of Pennsylvania, was dedicated in the afternoon of December 13 A memorial tablet to the donor, Dr Louis Adolphus Duhring, class of 1867, medical department, clinical professor, professor and finally emeritus professor, was unveiled at the entrance of the annex Brief addresses were made by Maurice Jastrow and Joseph T Rosengartner Provost Edgar F Smith accepted the building on behalf of the university The new wing extends across the south end of the library, is of red terra cotta and brick work, the design being in keeping with the old structure This addition is a emmorial to the late Dr Duhring, who left more than a million dollars to the university

TENNESSEE

Personal—Dr James W McClaran, Jackson, has accepted a position in a war hospital in Paris——Dr Henry Berlin, Chattanooga, is reported to be seriously ill at his home

Minnesota Surgeon in Chattanooga—Dr J Minor Blackford, Rochester, Minn, delivered an address on December 10 before the physicians of Chattanooga on "Newer Cardiac Pathology and Diagnosis," illustrated by moving pictures

Physician Wins Suit—In the suit brought by the father of Hyram Henderson, Potts Camp, Miss, against Dr Frank D Smythe, Memphis, in which damages for $20,000 were claimed on account of negligence in performing a surgical operation, the jury rendered a verdict December 3, in favor of Dr Smythe

State Board Officers Reelected—At the annual meeting of the State Board of Health held in Nashville, November 6, the following officers were reelected Dr Rufus E Fort, Nashville, president, Dr Walter J Miller, Johnson City, vice president, and Dr Reese Q Lillard, Lebanon, secretary and executive officer

New Officers for Middle Tennessee Association—The forty-third semiannual meeting of the Middle Tennessee Association was held at Sparta, November 18 and 19 Dr Roy W Billington, Nashville, was elected president, Dr W Scott Farmer, Cookeville, vice president, and Dr John Witherspoon, Nashville, secretary-treasurer Lewisburg was selected as the next place of meeting

Sanatorium at State Prison Opened—The new modern tuberculosis hospital connected with the State Prison, Nashville, which has been erected at a cost of $40,000, was opened December 4 and 125 infected state prisoners were installed in the new institution Hereafter, all prisoners sent to the penitentiary will be carefully examined for tuberculosis at the time of their admission

Preventable Blindness—The campaign against preventable blindness is being pushed vigorously by organizations in Nashville A pamphlet has been prepared giving the state law on the subject, outlining the methods of preventing blindness in infants, and laying emphasis on the importance of the subject The pamphlet has been endorsed by the State Board of Health and the Nashville health authorities

TEXAS

Drug Law Violations—In the federal court at Fort Worth December 6, fourteen persons were sent to jail for violation of the antinarcotic law

North Texas Physicians Hold Meeting—The North Texas Medical Association held its annual meeting in Fort Worth December 7 and 8, and adjourned to meet in Greenville in June. Dr Charles R Johnson Gainsville, was elected president, Dr Claude O Harper, Fort Worth, vice president, Dr H Leslie Moore, Dallas, secretary (reelected for the thirty-second term), and Dr John H McLean, Fort Worth, treasurer

Diphtheria.—In October diphtheria was reported from fifty-three of the 252 counties in the state, the largest number of cases in any one county being forty one. There was a total of 554 cases Under contract made by the State Board of Health, antitoxin approved by the United States Public Health Service costs patients $4 per 10 000 units as against $12 50, the price formerly charged It has been concluded that if an average of 15,000 units was used in each case of diphtheria, at the new price there would be a saving of over $7,000 to the people of the state Distributing stations have been established in every *county of the state, although it is* believed the people are not all aware of this arrangement for distributing antitoxin

CANADA

Word from Saloniki.—The Toronto University Base Hospital is located 5 miles north of Saloniki on the road to Monastir Directly in front of their camp is the railroad to Nish At the present time there are about 500 patients, very few wounded soldiers, but mostly cases of typhoid dysentery and influenza.

Germany Refuses to Liberate Hon Dr Beland—The German government has refused to liberate the Hon Dr Beland, former postmaster-general of Canada who was captured at the fall of Antwerp They are willing however, to exchange him for a lieutenant of the German Army now in the London Tower under sentence of death for espionage

Canadian Appointments—The following Canadian physicians have been gazetted lieutenants R A. M C Drs C E Wilson, H C. Sutton, H B Moyle, H P Rogers, A W Nixon and H B Stacpoole, all of the Canadian Army Medical Corps——Drs James Donald, M MacAdam and Norman Ferguson have been appointed captains in the army service corps——Major J T Clarke, M D., formerly a practitioner in Toronto has been promoted to lieutenant-colonel and has been placed in charge of No 2 Stationary Hospital, Boulogne, France.

Toronto Convalescent Home Staff—For the returned soldiers in Toronto the medical staff of the Convalescent Home is being chosen by Lieut.-Cols Herbert A Bruce and Harry B Anderson, who will be chief surgeon and physician, respectively The following are the appointments so far named Drs Herbert J Hamilton, Goldwin Howland Jabez H Elliott, Brefney O Reilly, Robert W Mann, Harold Tovell, William J McCollum, D J Gibb Wishhart, Colin Campbell, George H. Burnham Newbold Jones, John A Oille, Arthur Wright, Charles B Shuttleworth, A. Muirhead, Charles Temple and Albert E Webster, M D, D D S

University Looks for Government Aid.—A deputation from Queen's University, Kingston, Ont, recently waited on the premier of Ontario and the provincial treasurer to ascertain the attitude of the government toward the future of that institution Three years ago Queen s severed its connection with the Presbyterian Church in Canada and following that the Mining School agreed to affiliate with the University The Ontario government has been giving Queen's an annual grant of $70 000 for the mining and medical branches On account of war conditions Queen s will have a deficit for the current year of $30 000, the large number of enlistments from the student body having brought about a decreased attendance and a consequent decrease in the fees received The government has promised to consider the matter

GENERAL

Correction—In the article by Woodyatt, Wilder and Sansum, The Journal, December 11, p 2068—the last sentence of the first paragraph second column, p 2069, should read—But if the glucose is given at a rate faster than 2 gm per kilogram and hour 50 per cent of all glucose injected appears in the urine, once constant conditions have been secured In the third paragraph the figures 3 6 gm should be 2 7 gm

Roentgenologists Unite—About seventy-five roentgenologists from Illinois, Indiana, Iowa, Missouri and Kentucky met in Chicago, December 15 and 16, and organized the Western Roentgen Society, electing the following officers president, Dr Fred S O'Hara, Springfield, Ill, vice presidents, Drs Miles B Titterington, St Louis, and Noble M Eberhart Chicago, secretary, Dr Thomas A Burcham, Des Moines, and treasurer Howard Raper, D D S, Indianapolis The next meeting will be held in Chicago, June 15 and 16, 1916

Compensation for Federal Employees—The American Association for Labor Legislation announces that the Kern-McGillicuddy Bill to provide just compensation for federal employees will be introduced into the new congress at an early day This bill, which was reported favorably by the judiciary committee of the last congress and has been endorsed by the Federal Bureau of Labor Statistics, American Federation of Labor and other bodies, was drafted to supersede the law of 1908 Nearly three quarters of the half million employees of the United States are not entitled to any compensation whatever for injuries and moreover, no injured workman can sue the national government for liability In the present year, eight states have adopted the workman's compensation bill far in advance of the existing law for federal employees while five of the thirty-three states which have workman's compensation law have adopted liberal and progressive amendments

Examination for Philippine Service—The United States Civil Service Commission announced that open competitive examinations will be held on January 8, for the positions of bacteriologist and pathologist (male), with a salary of $2 000 to $2,500 a year, and for assistant surgeon (male), with a salary of $1 800 a year The competitors will not be assembled for examination, but will be rated on education, experience and publication or thesis Applicants must be graduates in medicine and must have had special training in bacteriology, must be between 21 and 40 years of age, and must have executed the prescribed medical certificate Persons who meet the requirements and desire the examination, should apply for Form B I.A 2 and 2118 stating the title of the examination for which the forms are desired, and these applications should be sent to the United States Civil Service Commission at Washington, or to the secretary of any local United States Civil Service Board They must be filed prior to the hour of closing business on January 18

Deaths Abroad—Kenneth William Millican, M R C S, England, 1879, L R C P, Edinburgh 1880, for two years a member of the editorial staff of The Journal, died at his home in West Kensington London, November 28, aged 62 After graduating in medicine, Dr Millican was for several years an officer of the Royal Army Medical Corps in India and Africa and then came to this country While here he acted as associate editor of the *New York Medical Journal,* under the late Dr Frank P Foster, editor of the *St Louis Medical Review* and later became associated with The Journal In *1909* he returned to St Louis for a short time as editor of the *Bulletin of the Municipal Commission on Tuberculosis* and then returned to England as a member of the editorial staff of the *Lancet* Dr Millican's society affiliations included Fellowship in the American Medical Association and membership in the British Medical Association Missouri State Medical Association and St Louis Medical Society, of which he was once president Dr Millican was a gentleman of charming personality, a scientist of high rank and a writer of high literary ability

Death Rate in Registration Area in 1914—According to a bulletin issued by the Bureau of the Census, the total number of deaths recorded in the registration area in 1914 was 898,059 corresponding to a death rate of 13 6 per thousand population This rate is said to be the lowest on record, the next lowest being for the year 1912 when the rate was 13 9 This has added significance by reason of the fact that the number of states in the registration area has increased since 1912, the number now being twenty-five, comprising 66 8 per cent. of the total estimated *population in* the United States in 1914 The death rate for 1914 is said to be 16 per cent lower than the average for the five year period of 1901-1905 This means that in 1914 there were only 10 deaths, where ten years earlier there were 11 deaths Decreases in the death rate in the number of states of the registration area in 1914 as compared with 1901-1905 period are as follows Rhode Island, 17 4 *per cent*, *New York, 14*, *New Jersey* 11.8 Massachusetts, 11 4, Vermont, 7 4, Connecticut 3.8 Indiana 2 3 Maine, 1 9, and New Hampshire 1.8 Michigan showed a slight increase, 0 8 *per cent* It is shown that in cities of 100,000 or over the tendency is toward a still greater reduction In comparing the five year period 1901-1905 with 1914, the following reductions were shown in cities Jersey City, 28 5 per cent, New York, 25 8, San Francisco, 23 6, Denver, 23 3, Newark, N J, 22 5, Los Angeles, 21 3, Pittsburgh, 21 9, Atlanta, Ga, 21 8, Lowell, Mass, 21 3, and Paterson, N J, 20 1 The caution is given that these figures are crude rates and that inferences regarding the relative health advantages of different states should not be drawn without more thorough investigation

Report of the Surgeon-General of the U S P H S—The advance summary of the annual report of the surgeon-general shows that the organization under the broadened functions assigned to it by the law of 1912 has made possible the largest amount of work in its history Among the notable features of this work for 1915 enumerated in the summary are the conclusion, after seven years of investigation, that pellagra is a deprivation disease, the establishment of a new quarantine station at Galveston, and the transference of the station at Boston to the Public Health Service, eradication of plague from New Orleans, and the establishing of extensive rat-proofing and other antiplague measures, great reduction in the incidence of malaria where surveys were conducted, and the establishment in this connection of the fact that malaria is carried over the winter by persons infected with the disease rather than by hibernating mosquitoes, important knowledge gained from the study of occupational diseases and tuberculosis among industrial workers, and relating to the migration of persons suffering from tuberculosis, improvement in the powers and duties of health boards in five states, on the recommendations of the Public Health Service, investigation of the pollution of streams and the examination of shellfish, important studies of trachoma in the Appalachian Mountains, where over 12,000 cases were treated, rural sanitation work in six different states, resulting in the reduction of typhoid and other communicable diseases, and the establishment at Chicago, Seattle and other railway centers of public health laboratories for the prevention of the interstate spread of disease On account of the extension of relief benefits to the newly organized Coast Guard and the physical examination of seamen applying for the rating of "able seamen," the service asks for an increased force to take care of this additional work An additional building for the Hygienic Laboratory and the establishment of a national leprosarium are also recommended in the report

Bequests and Donations—The following bequests and donations have recently been announced

Harvard College, $75,000, the remainder of the bequest of Morrill Wyman to establish the Morrill Wyman Research Fund, the income to be applied to investigation by Harvard Medical School, into the origin, results, prevention and treatment of disease

Harvard Unit in France, $4,000, American Ambulance Field Service fund, $4,000, and New England Belgium relief fund, $3,537 39, being the amount collected in the stadium at the Harvard Yale football game

Children's Hospital, Brookline, Mass, $3,000 Boston Floating Hospital, $2,000, and Angell Memorial Animal Hospital, $2,000 by the will of Edward Friebe, Cohasset, Mass

Americus, Ga, Hospital Association, $2,500 by Mr and Mrs Frank Lanier, Americus, in memory of their son who died November 25

James Walker Memorial Hospital, Wilmington, N C, an annex for the treatment of children and nursing mothers, erected by Mr and Mrs James Sprunt, Wilmington, as a memorial to their deceased daughter, to cost $30,000

School of Medicine, of the University of Kansas, Rosedale, the balance of the estate of Dr Joseph Porter, Paola, appraised at from $27,000 to $37,000 the income only from this fund to be used, and of the income, $300 is to be used for a scholarship, the remainder to be used as thought advisable by the dean

University of Kansas, Rosedale, donations of three acres of land to be added to the campus from the Bell estate, Dr Marshall A Barber, Rosedale, and Mr H L Rose

United Hebrew Charities and Mount Sinai Hospital, New York City, each $2,500, Montefiore Home, $2,000, Home for Aged and Infirm Hebrews, Hebrew Infirmary and German Hospital, each $1,500 by the will of Bernhard Ulmann

Eaglesville (Pa) Sanatorium for Consumptives, about $4,000, the proceeds of a card party and dance given December 8, under the auspices of the Ladies' Auxiliary of that institution

Abbington (Pa) Memorial Hospital, a nurses' home to cost $50,000, on property adjoining the hospital, donated by George W Elkin, Sr, in memory of his wife

University of Pennsylvania for the use of its hospital, two ninths of the residue of the estate of William B Rawle, after the death of Mrs Rawle Children's Hospital, Philadelphia, establishment of a free bed to be known as the Charles Wallace Brocke Jr, free bed, by the will of the mother of Mr Rawle on the death of his wife

Children's Aid Society, Country Week Association, Society for Protection of Children from Cruelty, and Sanatorium Association for Children, $4,000 each, by the will of Henry A Rogers

Children's Hospital, Philadelphia, a bequest of $10,000 for the endowment of a free bed in memory of her son George, by the will of Emily M Price

Women's Homeopathic Hospital, $5,000, by the will of Mary E Harbeson

American Oncologic Hospital and Kensington Dispensary, each $1,000, by the will of Maggie Green

LONDON LETTER

London, Nov 26, 1915

The War

THE TYPHOID GROUP OF DISEASES

The immense experience of the war is extending our knowledge of disease in several directions In previous letters it has been shown that, thanks to the excellence of medical arrangements, and to inoculation in particular, the incidence of typhoid fever among the troops has been very low The fact has come to light that a good many of the cases which clinically appeared to be typhoid fever were examples of paratyphoid fever Thus, in a recent discussion at the Royal Society of Medicine, Sir Bertrand Dawson stated that of 1,636 cases first regarded as typhoid fever, 910 proved to be paratyphoid Among them were many of the form of paratyphoid A which is little known in this country though common in India, the form paratyphoid B has been recognized in England for some time Observations in regard to inoculation tend to confirm the specificity of the several pathogenic micro-organisms responsible for the various forms of infectious disease Thus it has been shown that inoculation against typhoid infection does not confer immunity to paratyphoid, and that inoculation against the one infection does not increase susceptibility to the other It would seem that safety can be secured only by a number of inoculations, each directed to a specific end However, quite satisfactory results follow the practice of simultaneous mixed inoculation Thus Professor Dreyer reports that the injection of a vaccine containing in certain proportions the typhoid bacillus, paratyphoid bacillus A and paratyphoid bacillus B is followed in some cases by protection against all the three infections and in other cases by protection against two of them, and this without any greater immediate disturbance than is common in the ordinary antityphoid inoculation Professor Castellani has gone further and has used what he calls a tetravaccine, which aims at protection not only against the three infections mentioned but also against cholera His experience in Serbia includes 50,000 men, and he reports absence of immediate ill effects and the practical absence from the inoculated troops of the diseases in question

THE CARE OF THE BLIND SOLDIER

Soon after the outbreak of the war, the need was recognized of an institution for those sad cases of loss of the sight of both eyes from the injuries of warfare The Hostel of St Dunstan's, Regent's Park, London, was established, and is being maintained by the National Institute for the Blind, the British Red Cross, and the Order of St John of Jerusalem The Hostel, which was given by Mr Otto Kahn, stands in about 15 acres of ground It includes a portion of the Regent's Park lake, which affords facilities for rowing—a pastime keenly appreciated by the blind inmates The men come from the various military hospitals, and are afforded the opportunity of learning a trade by which they may earn a livelihood The occupations taught include carpentry, boot repairing, mat and basket making massage and telephony An interesting adjunct to the institution is the model farm, under the care of Captain Webber, a blind expert Here the men are taught market gardening, bee keeping and poultry farming, and by clever devices it is possible for the patients to carry on the work with success After a short period of training they can drive birds from one pen to another, catch any particular fowl, and collect eggs Arrangements have also been made for attendance at a neighboring public bath on certain days The exercise of swimming is much enjoyed by the men, and some of those who were nonswimmers are rapidly becoming experts in the art The Council of the National Institute for the Blind has placed at the disposal of the committee its seaside home at Brighton, where men can be sent to recuperate after discharge from hospital and previous to their taking up their training

THE RECRUITING OF MEDICAL STUDENTS

A scheme of recruiting the whole country for the army has been adopted Fit men are given the option of joining the army at once or being attested and placed in one of forty-six groups of all those aged from 18 to 40 years There are twenty-three groups for single men (each year of age constitutes a separate group) and twenty-three similar groups for married men The first group consists of single men aged 18, the forty-sixth group of married men aged 40 It is proposed to call the men up in the numerical order of the groups, except that men of 18 will not be called up for service until they have attained the age of 19 The special case of the medical student has given rise to a good deal of discussion As stated in a previous letter the War Office decided that in consequence of the great shortage of physicians, fourth and fifth year students should proceed with their course and qualify as soon as possible so as to be able to enter the army as surgeons On the other hand, students in the first, second and third years should if physically fit, join the army as combatants Exception has been taken to this rule because of the shortage of physicians which it will create in future years by withdrawing so many students from their studies But the authorities pointed out that the need of the army must be paramount at the present moment and that medical students who are generally men of good physique and full of spirit and courage make admirable combatant officers However some extension of exemption has been granted in the latest announcement from the War Office Students who at or before the close of the present winter session will be qualified for entry to one of the examinations for the third year students in medicine and duly enter for the examination for which they are studying will not be attested until after its conclusion and if they are successful will be included in the class of fourth year men.

THE BIRTH RATE AND THE WAR

At the Royal Sanitary Institute Dr Louis C. Parkes a well-known health officer and authority on hygiene read a paper on the national and social aspect of the lowered birth rate He said the birth rates of nearly all the European nations had been steadily decreasing during the past thirty years He estimated the total destruction of life in Europe in two years of war at nearly 20 000 000 persons. But in past ages of the world's history evolution of higher types in animal and vegetable life had resulted from cataclysmic changes, and great destruction by plague pestilence and famine had led to an advance in civilization So it was possible that Armageddon might be of ultimate benefit to humanity The figures for England and Wales for the past forty years showed that on the whole the birth rate had been falling faster than the death rate and the mean rate of increase, except for the first few years of the present century showed a downward tendency There was foundation for the belief that the lowering of the birth rate had been specially marked among the upper, the middle and the superior working classes Tables giving mean birth rates among other nations for the years 1910-1912 showed generally that nations largely agricultural had the highest birth rates while in the more highly industrialized countries the birth rates were lower With the exception of Bulgaria with a decided increase in the rate of 3.6, and of Ireland and Roumania, with very slight increases most of the nations which furnished statistics showed lowered birth rates in the course of the last quarter of a century After the war a government commission should be appointed to make exhaustive inquiry into the whole question with a view to taking measures of social and economic amelioration With a happy combination of circumstances the country should start a new life and the replenishment of its young life on a sufficiently ample scale might be anticipated

Tuberculosis in the Boot and Shoe Industry

There is an unusually high incidence of tuberculosis in the boot and shoe industry The means of dealing with this has been investigated by the Medical Research Committee appointed under the national insurance act for such purposes The high mortality is attributed to several factors among these being the sedentary nature of the employment and the attitude adopted, the presence of infected workers who are by circumstances favorably placed for disseminating bacilli among their neighbors the lack of sufficient daylight and adequate ventilation and the presence of infected dust The economic as well as hygienic advantage of so-called play intervals is insisted on A quarter of an hour interval at 11 a m and again at 4 p m is suggested and opportunity for Swedish drill or for games It has been shown that more and better work is done with than without such intervals The importance of ventilation and keeping the factories adequately cool is also insisted on

BERLIN LETTER

Berlin Nov 9, 1915

Birth Rate and Nurslings' Mortality in the Large German Cities During the War Period

The records of the imperial health bureaus of twenty-six German cities having more than 200 000 inhabitants show as was to be expected, that with the beginning of the tenth month of the war the number of living new born has diminished considerably For instance, in Berlin during the month of April the birth rate was 17 against 79 in the same month of the previous year Exactly nine months after the declaration of war during the first week of May, 99 fewer children were born in Berlin than during the previous year In the second week 138 and in the last week of May 198 fewer children were born and during the second week of June the decrease was 244 This is the height of the growth of the lowering of the birth rate The diminution thereafter was usually below 200 In the other large cities there was in part an increase during the month of April but beginning with May there was a considerable diminution The one exception is the city of Essen but even here the increase in the number of births was due to an increase in population In Cologne the diminution was the least but here, as in Essen the death rate during the first year of life was increased Elsewhere this death rate was diminished One must not construe however that there was a general falling off in the death rate of infants because arriving at such a conclusion one must estimate how many deaths occur among the nurslings born during that time

Value of Prophylactic Immunization in Typhoid

During the Franco-Prussian war there were 74 205 cases of typhoid from 8 to 9 per cent of the whole number of soldiers There were 8 904 deaths, or about 1 per cent, of the total strength of the army More than one half, 60 per cent, of the total loss for all the troops was caused by typhoid The observations made during the prophylactic immunization of the troops in Southwest Africa showed that among protected soldiers there were fewer and less severe cases of typhoid than among the unvaccinated soldiers The death rate among the vaccinated was 4 per cent, among the unvaccinated 11.1 per cent Therefore vaccination against typhoid is not an absolute protection against the disease but typhoid in a vaccinated person runs a very mild and much more favorable course. In those vaccinated more than once the course of the disease was even more favorable Positive conclusions as to the value of such vaccination in the present war cannot as yet be drawn but the numerous observations that have been made enable one to express an opinion as to the value of this prophylactic immunization Goldscheider and Koner have reported that in addition to vaccination prophylactic sanitary measures were prescribed and to these a large measure of the success obtained must be ascribed The vaccination therefore was only an operating factor in the reduction of the number of cases of typhoid and the death rate from typhoid The course of the fever was much less severe among the vaccinated than among the unvaccinated The temperature was lower but the duration of the fever was not appreciably shortened There is almost a complete absence of headache, restlessness and delirium and convalescence is rather rapid Fewer complications are met with among the vaccinated, especially is this true of the disastrous effects on the heart muscle and when complications did occur they were much less severe Among the soldiers vaccinated twice the course of the disease was even more favorable Among the vaccinated the death rate was 6.9 per cent., among the unvaccinated the death rate was 12 per cent One must not forget that the general hygienic prophylaxis which can be carried out during war time is not comparable with the prophylaxis in time of peace and therefore the prophylactic immunization against typhoid undoubtedly is of much greater value in peace than in war However we must admit that such immunization is of very great value especially in war times

---

Marriages

Charles John Hufnagel, M D to Miss Lucina Kirst, both of Cannelton Ind., November 25

Philip Newton M D., Washington D C., to Princess Shahofskaya of Petrograd, Russia recently

Walter S Clack M D to Miss Elizabeth Haley, both of Rockwood Tenn December 8

Clara Pauline Seippel, M D, to Robert A. Widdowson, both of Chicago in Minneapolis December 11

Frank Murray Scheele, M D, Waukesha Wis., to Miss Emma Edmonds of Wauwatosa, Wis, December 1

Allen Wheeler Holmes M D., Dansville N Y., to Miss Clara Lillian Merrill of Hamilton Mass December 7

Margaret Cartwright M D to Joel B Good, both of Albuquerque, N M November 30

F Stuart Graves M D to Miss Louise Brown, both of Louisville, Ky., December 11

Deaths

George Peaslee Shears, M D New York University, New York City, 1886, aged 53, a member of the Medical Society of the State of New York, clinical professor of obstetrics in the New York Polyclinic Medical School, chairman of the board of directors of the City Hospital, Blackwell's Island, attending obstetrician to the City, Misericordia and New York Polyclinic hospitals, died at his home in New York City, December 12, from cerebral hemorrhage

Edward H Thrailkill, M D Kansas City Medical College, Kansas City, Mo, 1890, aged 52, a Fellow of the American Medical Association, professor of rectal surgery in the University of Kansas, rectal surgeon to St Joseph's and the Swedish hospitals, Kansas City, proprietor and manager of Thrailkill's Sanitarium for Diseases of the Rectum, Kansas City, died at his home in Kansas City, December 7, from the effects of an overdose of chloroform

Frank Joseph Sykora, M D Chicago College of Medicine and Surgery, 1909, aged 38, formerly a Fellow of the American Medical Association, a member of the Minnesota State Medical Association and well-known as a surgeon of Brainerd Minn, a director of the Brainerd City Bank, died in St Joseph's Hospital, St Paul, November 17, from disease of the intestines for which three operations had been performed

Erastus Perry Swazey, M D College of Physicians and Surgeons in the City of New York, 1869, aged 68, a Fellow of the American Medical Association and a well-known practitioner of New Britain, Conn, who had been ill for a long time with disease of the heart and kidney, died at his home in New Britain, November 13, from cerebral hemorrhage

James Irving Cawley, M D University of Pennsylvania, Philadelphia, 1877, aged 62, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of Pennsylvania, register of wills of Bucks County, Pa, and postmaster of Springtown where he had practiced for thirty-six years, died at his home December 10

Michael M Leahy, M D University of Glasgow, Scotland, 1857, University of Dublin, Ireland, 1862, Jefferson Medical College, 1883, aged 75, a Fellow of the American Medical Association, for many years a practitioner of Chicago, but for the last twenty years a resident of Montana, died at his home in Anaconda, Mont, December 15

George K Binkley, M D University of Pennsylvania, Philadelphia, 1873, aged 69, a Fellow of the American Medical Association, president of the Schuylkill County (Pa) Medical Society, a veteran of the Civil War and a well-known practitioner and druggist of Orwigsburg, Pa, died at his home in that place, December 4

William Brewster Millwee, M D Castleton (Vt) Medical College, 1848, aged 89, one of the oldest practitioners of Greenwood County, S C, first president of the Greenwood Oil Mill and vice president of the Bank of Greenwood, once mayor of Williamston, died at his home in Greenwood, December 1

Benjamin H Perce, M D Medical College of Indiana, Indianapolis, 1873, aged 77, a member of the Indiana State Medical Association and for two terms president of the Madison County Medical Society, a veteran of the Civil War, died at his home in Anderson, Ind., December 3, from nephritis

Lewis Frey, M D University of Pennsylvania, Philadelphia, 1888, aged 52, formerly a Fellow of the American Medical Association, visiting physician to the State Hospital and the Consumptive Hospital, Scranton, Pa, died suddenly at his home in Scranton, December 6, from angina pectoris

C Robert Martin, M D Miami Medical College, Cincinnati, 1866, aged 73, one of the oldest practitioners and druggists of Henry County, Ky, and one of the directors of the Deposit Bank of Sulphur, Ky, died at his home in that place, December 9, from cerebral hemorrhage

Ira Dean Payne, M D University of Iowa, Iowa City, 1880, Bellevue Hospital Medical College, 1886, aged 63, who after many years of practice in Linton, Iowa, retired five years ago and moved to Des Moines, died at his home in that city, September 7, from heart disease

James E Gauline (license, Maryland), for more than twenty-two years connected with the Home Friendless Society, Waverly, Baltimore, died at his home in that place, December 3, from cerebral hemorrhage

James Garrett Linthicum, M D University of Maryland, Baltimore, 1859, aged 81, formerly professor of the practice of medicine in Baltimore University, a member of the Baltimore city council for four terms, died at his home in West Baltimore, December 7, from pneumonia

Jesse Lincoln Melton, M D Hospital College of Medicine, Louisville, 1902, aged 55, formerly a member of the Kentucky State Medical Association, and until a year ago a practitioner of Shelbyville, Ky, died at his home in Louisville, December 10, from typhoid fever

Rhys Williams, M D Western Pennsylvania Medical College, Pittsburgh, 1894, aged 46, of Federal, Pa, for twenty years a practitioner of the Bridgeville District and director of the Bridgeville Trust Company, died at his home in Federal, about December 11

John A. Kirkland, M D Jefferson Medical College, 1885, aged 59, a Fellow of the American Medical Association, for many years a member of the school board of Cambridge, Ill, and a well-known ornithologist, died at his home in Cambridge, December 10

Henry Manning Fish, M D Hahnemann Medical College, Chicago, 1900, aged 62, a Fellow of the American Medical Association and American Academy of Ophthalmology and Oto-Laryngology, a well-known specialist, died at his home in Chicago, December 11, from pneumonia

Ellis Henry Bishop, M D Bennett Medical College, Chicago, 1905, aged 43, a Fellow of the American Medical Association, died at his home in Neponset, Ill, December 5, from an overdose of medicine taken for the relief of acute gastritis

Carl Martinus Nielsen, M D University of Copenhagen, Denmark, 1885, Bennett Medical College, Chicago, 1893, aged 59, president of the Scandinavian-American Medical Society, Chicago, died at his home in that city, December 14

Lloyd McDonald Burgess, M D Marion-Sims Medical College, St Louis, 1893, aged 44, a Fellow of the American Medical Association, died at his home in Delta, Colo, September 5, six months after an operation for cholecystitis

John W Davis, M D Georgetown University, Washington, D C, 1860, aged 78, a veteran of the Civil War, and a resident of Lansing, Iowa, for more than fifty years, died at his home in Lansing, December 6, from heart disease

John Jackson Esmond, M D University of Toronto, 1877, aged 63, for several years a practitioner and postmaster of Tracy, Mo, but for nearly twenty years a practitioner of Kansas City, Mo, died at his home in that city, December 8

P Watt Cate (license, Tennessee, 1889), aged 61, for thirty-two years a practitioner of Charleston, Tenn, but who made his home for two years with his daughter at Solano, N M, died at his home near Charleston, December 10

Lomax Anderson, M D University of Alabama, Mobile, 1879, aged 69, a Confederate veteran and an active practitioner of Jackson, Miss, until his retirement in 1908, died at his home in that city, December 9, from nephritis

Jacob B Lewis, M D Eclectic Medical Institute, Cincinnati, 1893, aged 44, formerly of Boise, Idaho, and for four years physician of Ada County, died on his stock ranch near Meridian, Idaho, December 5, from pneumonia

Jeremiah Elwood Sayre, M D Jefferson Medical College, 1883, aged 63, for twenty-five years a member of the board of education of Red Bank, N J, died at his home in that place, December 11, from cerebral hemorrhage

Wiley M Baird, M D University of Nashville, Tenn, 1861, aged 75, a Confederate veteran and for one term state senator from the Jackson County District, Ark, died at his home in Bentonville, Ark, December 4

George W Haislip, M D Jefferson Medical College, 1882, aged 57, a member of the Medical Society of Virginia and a well-known practitioner of Lorton, Va, died in the Sibley Hospital, Washington, D C, December 5

Richard James Sadlier Wheeler, M D L R C P, L R C S, Edinburgh, 1884, M D, University of Edinburgh, 1894, aged 53, of Birtle, Man, died in the Winnipeg General Hospital, September 17, from cerebral hemorrhage

Joseph Etienne Gendron, M D Dartmouth Medical School, Hanover, N H, 1871, aged 72, of Worcester, Mass, died in St Vincent's Hospital in that city, October 5, from intestinal obstruction

Samuel C Corbett, M D Victoria University, Coburg, Ont, 1867, aged 70, a resident of Winnipeg, Manitoba, from 1882 until a short time ago, died at Vancouver, B C, September 18

Thomas Miller, M D Howard University, Washington, D C, 1884, aged 58, a member of the Medical Society of the District of Columbia, lecturer on anatomy and diseases of children in his alma mater, died at his home in Washington, November 30

William Lewis Suesholtz, M D Long Island College Hospital, Brooklyn, 1907, aged 43, a member of the Medical Society of the State of New York died at his home in Brooklyn, November 26, from the effects of an overdose of acetanilid

Frank D Wheeler, M D Detroit Medical College, 1880, aged 60, a Fellow of the American Medical Association and prominently identified with the medical work of Detroit for more than thirty years, died at his home in Detroit, November 27

Laura J Ross Wolcott, M D Women's Medical College of Pennsylvania, Philadelphia, 1856, aged 82, said to have been the third woman in the United States to receive a degree in medicine, died at her home in Chicago, December 8

Francis Coffin Martin, M D Harvard Medical School, 1883, aged 57, formerly a member of the Massachusetts Medical Society and a Fellow of the American Academy of Medicine, died at his home in Roxbury, Boston, December 3

Freeman Hardin Hornibrook, M D College of Physicians and Surgeons, Chicago, 1902, aged 37, a member of the Iowa State Medical Society, was found dead at his home in Cherokee, Iowa, November 30, from cerebral hemorrhage

Patrick Henry Bumster, M.D New York University New York City, 1893 aged 56, visiting physician to St John's Hospital Long Island City, N Y, died at his home in Long Island City, December 1, from hemorrhage of the stomach

Patrick J Marren, M D Medico-Chirurgical College of Philadelphia, 1896, aged 43, a member of the Medical Society of the State of Pennsylvania, died at his home in Bellevue, Pittsburgh, November 28 from pneumonia

William E Scriber, M D Michigan College of Medicine, Detroit, 1883, aged 46, a member of the Michigan State Medical Society, died at his home in Detroit, December 3, from septicemia following a carbuncle of the neck

John H Ashcraft, M D Jefferson Medical College, 1855, aged 82, an honorary member of the Gloucester County, N J, Medical Society, died at his home in Mullica Hill, N J, September 26, from carcinoma of the back

Louis Lee Abbott, M D Tulane University, New Orleans, 1898, aged 52, a member of the Louisiana State Medical Association, a practitioner and druggist of New Orleans, died at his home in that city November 30

John Wallace Allison, M D Cincinnati College of Medicine and Surgery 1877 aged 62, twice a representative from Kankakee County in the Illinois State Legislature, died at his home in Essex, Ill., December 4

Hiram Parker Trull, M D University of Buffalo, N Y, 1868, aged 73, a member of the Medical Society of the State of New York, died at his home in Williamsville, N Y, September 14, from arteriosclerosis

Nathaniel A Gray (license, Milwaukee, 1899), aged 75, a member of the State Medical Society of Milwaukee and a practitioner since 1867, died at his home in Milwaukee, November 25, from pneumonia

Stephen Horace Murphy, M D Bellevue Hospital Medical College 1879, aged 62, until 1904 a practitioner of New York state, died at his home in Spokane, Wash., November 11, from carcinoma of the palate

Francis O Hawley, M D University of Edinburgh, Scotland 1868 aged 69, city physician and health officer of Charlotte N C, died at his home in that city, September 14, from cerebral hemorrhage

C Beverly Martin, M D Hospital College of Medicine, Louisville, 1903, aged 35, a member of the Kentucky State Medical Association, died suddenly at his home in Greenville, Ky., December 1

Lewis Lanzer, M D Eclectic Medical College of the City of New York, 1892, University of Tennessee, Nashville, 1896, aged 50, died at his home in Brooklyn, December 3, from diabetes

James S Miller, M D University of Louisville, Ky., 1877, aged 62, president of the Titus County (Texas) Medical Society in 1910, died at his home in Mt Pleasant, Texas, November 28

Jule E Marcus, M D Cincinnati College of Medicine and Surgery, 1871, aged 64, a member of the Ohio State Medical Association, died at his home in Walnut Hill, Cincinnati, December 6

Alexander C Faivre (license, Crawford County, Pa, 1881), aged 78, for many years a practitioner of Meadville, Pa, died at the home of his daughter in that city, November 26

Abraham Turner Fulton, M D New York University, New York City, 1882, aged 60, of Mount Vernon, Ohio, died in the Mount Vernon Hospital, November 29, from nephritis

Erner Jones, M D Memphis Hospital Medical College, 1882, aged 38, formerly a member of the Arkansas Medical Society, died at his home in Harrell, Ark, November 28

Brice M Sprayberry, M D Georgia College of Eclectic Medicine and Surgery, Atlanta, 1882, aged 68, died at his home near Ellenwood Ga, December 4, from nephritis

Gabriel F Thornhill, M D Hering Medical College, Chicago, 1898, aged 56, of Paris, Texas, died suddenly, in his automobile, December 6, from cerebral hemorrhage

Joseph A Kohout, M D University of Nebraska, Omaha, 1905, aged 35, formerly of Ord, Neb, died at his home in Cuba, Kan, about November 10, from tuberculosis

George Besson McCosh, M D Rush Medical College, 1880, aged 58, a practitioner and druggist of Morris, Ill, died at his home in that place, December 5

George Henry Wilkins, M D New York Homeopathic Medical College New York City, 1883, aged 60, died at his home in Newtonville, Mass, November 17

Bernhardt S Schwarz, M D American Medical College, St Louis 1897, aged 74, formerly of Kansas City, died at his home in San Francisco, December 6

Wesley Queen, M D Physio-Medical Institute, Cincinnati, 1864, aged 79, of Lincoln, Neb, died at his home in that city, December 12 from senile debility

Joseph Hormisdas Boucher, M D Laval University, Montreal 1884, aged 59, died at his home in Woonsocket, R I, September 25 from arteriosclerosis

Henry Miller Hewitt, M D Rush Medical College, 1878, of Franklin Grove, Ill, and Chicago, died at the home of his aunt in Dixon, Ill, November 29

Onofrio Abruzzo, M D College of Physicians and Surgeons in the City of New York, 1883, aged 74, died at his home in Brooklyn, December 7

Thomas Jefferson Slayden, M D Vanderbilt University, Nashville Tenn 1887, aged 55, died at his home in St Bethlehem Tenn., December 1

V R Kneberg, M D Homeopathic Medical College of St Louis, 1889, aged 66, died at her home in Chetoka, Kan, November 16, from peritonitis

William Martin Moran, M D Bellevue Hospital Medical College, 1887, aged 61, died at his home in Boston, September 2 from angina pectoris

George Slocomb Wilson, M D Eclectic Medical College of the City of New York, 1881, aged 76, died at his home in Boston, November 30

John B DesRochers (license, Washington, 1889), aged 66, formerly of Spokane, Wash, died at his home in Tacoma, Wash, December 2

Ella M Fowle, M D Hahnemann Medical College, Chicago 1893, aged 61, died at her home in Denver, November 25, from carcinoma

Henry T Fisher, M D Lincoln Memorial University, Knoxville, Tenn, 1891, aged 67, died at his home in Knoxville, November 27

John E Robinson, M D Louisville Medical College, 1876, aged 63, died at his home in Bethany, Miss, November 9, from paresis

Thomas R Allen, M D Homeopathic Hospital College, Cleveland, 1866, aged 71, of Ionia, Mich, died in Chicago, December 4

Stanard D Harris (license, Michigan, nineteen years' practice, 1900), aged 79, died at his home in Holly, Mich, December 1

Charles F Burger (license, years of practice, Michigan, 1900), aged 84, died at his home in St Clair, Mich., December 2

Silas C Myers (license, years of practice, Iowa, 1887), aged 64, died at his home in Waterloo, Iowa, November 29

Albo Miller, M D Jenner Medical College Chicago, 1904, aged 51, died at his home, December 1, from heart disease

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

POSLAM AND SOME OFFICIAL OINTMENTS

The following inquiry was recently made by a physician who asked that his name be omitted

> "One of my patients is anxious to learn something about Poslam, an alleged eczema cure I should like to know if the composition of Poslam has ever been published Are there any official products similar to it?"

Poslam was discussed in The Journal, May 22, 1909, page 1678 and on page 612 of "Nostrums and Quackery" (Second Edition) The results of a chemical analysis of this preparation made in the A M A Chemical Laboratory as published in these articles indicated that Poslam consisted of

Zinc oxid	12 01 parts
Sulphur	6 67 parts
Corn starch	22 00 parts
Tar oil	15 18 parts
Menthol	
Salicylic acid	
Fatty base, of each sufficient to make	100 00 parts

The results of the analysis were commented on as follows "From the results of the analysis it can be seen that the preparation depends for its action on such simple remedies as zinc oxid, sulphur and oil of tar These have long been used and known as more or less effectual remedies for the treatment of skin affections, but certainly do not warrant such claims as are made in the advertising matter sent out with poslam stating it to be 'The newest medical discovery for the treatment of eczema and all other skin affections' and ' entirely different from anything yet used ' "

For skin affections which may be benefited by ointments the official pastes and unguents should be kept in mind Needless to say these are as effective as the proprietary products and have the added advantage of being of known and more uniform composition Among the pastes may be mentioned

LASSAR'S NAPHTHOL PASTE
(Pasta Naphtholi, Lassar)

	gm or c c	
Betanaphthol (U S P), in very fine powder	10	gr xlviij
Precipitated sulphur (U S P)	50	ʒ iv
Petrolatum (U S P)	20	ʒ iss
Soft soap (U S P) sufficient to make	100	℥ j

Triturate the betanaphthol and sulphur with the petrolatum and then incorporate the soft soap with the mixture

LASSAR'S MILD RESORCIN PASTE
(Pasta Resorcini Mitis, Lassar)

	gm or c.c	
Resorcinol (U S P)	10	gr xlviij
Zinc oxid	25	ʒ ij
Starch	25	ʒ ij
Liquid petrolatum (U S P) sufficient to make	100	℥ j

Thoroughly levigate the zinc oxid with sufficient of the liquid petrolatum to make a thin paste Reduce the resorcin to a very fine powder, mix with the starch and add the mixture to the zinc oxid paste, triturating until a uniformly smooth mixture is obtained Then add the remainder of the liquid petrolatum, and incorporate it thoroughly

LASSAR'S ZINC-SALICYL PASTE
(Pasta Zinci, Lassar)

	gm or c c	
Salicylic acid, in fine powder	2	gr x
Zinc oxid	24	ʒ ij
Starch	24	ʒ ij
White petrolatum (U S P) sufficient to make	100	℥ j

Thoroughly levigate the zinc oxid with a portion of the petrolatum, then add the salicylic acid, the starch and the remaining petrolatum, and triturate until a perfectly smooth mixture is obtained

UNNA'S SOFT ZINC PASTE
(Pasta Zinci Mollis, Unna)

	gm. or c c.	
Zinc oxid	20	ʒ ij
Calcium carbonate	20	ʒ ij
Linseed oil	20	ʒ ij
Lime water sufficient to make	100	℥ j

Thoroughly levigate the zinc oxid and the calcium carbonate with the linseed oil, gradually added, so as to form a perfectly smooth mixture, then incorporate the lime water by trituration

UNNA'S SULPHURATED ZINC PASTE
(Pasta Zinci Sulphurata, Unna)

	gm or c.c	
Zinc oxid	15	gr lxxij
Precipitated sulphur (U S P)	10	gr xlviij
Silicic acid	5	gr xxiv
Benzoinated lard (U S P) sufficient to make	100	℥ j

Thoroughly levigate the zinc oxid with a small portion of the benzoinated lard, the silicic acid with another, and the precipitated sulphur with a third portion Mix the three portions until a uniformly smooth mixture results, and thoroughly incorporate the remainder of the benzoinated lard

COMPOUND RESORCIN OINTMENT
(Unguentum Resorcini Compositum)

	gm or c c	
Resorcinol (U S P)	6	gr xxx
Zinc oxid	6	gr xxx
Bismuth subnitrate	6	gr xxx
Oil of cade	12	ʒ j
Paraffin	10	ʒ j
Petrolatum	25	ʒ ij
Hydrous wool fat sufficient to make	100	℥ j

Triturate the resorcinol, zinc oxid, and bismuth subnitrate with a small quantity of the hydrous wool fat, until a perfectly smooth mixture is obtained Incorporate this with the remainder of the wool fat, add the paraffin and petrolatum, previously melted together, and lastly, the oil of cade Mix intimately, and preserve the ointment in containers protected from the light

COMPOUND SULPHUR OINTMENT
(Unguentum Sulphuris Compositum)

	gm or c.c.	
Precipitated calcium carbonate	10	gr xlviij
Sublimed sulphur	15	gr lxxij
Oil of cade	15	gr lxxij
Soft soap (U S P)	30	ʒ ij
Lard sufficient to make	100	℥ j

Mix the lard with the soft soap and oil of cade Then gradually incorporate the sublimed sulphur and precipitated calcium carbonate

COMPOUND TAR OINTMENT
(Unguentum Picis Compositum)

	gm or c c	
Oil of tar	4	gr xx
Tincture of benzoin (U S P)	2	gr x
Zinc oxid	3	gr xv
Yellow wax	25	ʒ ij
Lard	32	ʒ iiss
Cotton seed oil sufficient to make	100	℥ j

Melt the yellow wax and lard with the cotton seed oil at a gentle heat Add the tincture of benzoin, and continue heating until all the alcohol has evaporated Then withdraw the heat, add the oil of tar, and finally the zinc oxid, incorporating the latter thoroughly, so that on cooling, a smooth, homogeneous ointment may result

Correspondence

Effects of Athletic Competition on Childbirth

To the Editor —There seems to be a division of opinion among those interested in physical education as to the effects of strenuous athletic competition during adolescence on parturition The consensus of opinion, apparently supported by the fact that the foreign-born American woman or those actustomed to hard life have an easier labor than the American woman of nervous temperament, seems to be that athletics are beneficial at all times, except possibly at the menstrual periods

Besides the many factors, such as heredity, increased sensory conduction and reception, deficient muscular forces, etc, that influence childbirth, I believe there is a marked difference on the pelvis in the physiologic effect of the exercise performed

The type of exercise (work) of the working woman has its predominating effect on the musculatures of the trunk and upper extremities The movements are invariably rhythmic, slow and continued over a long period of time with a minimum stress and strain on the pelvis The character of athletic movements is entirely different Here the body weight is quickly shifted from one foot to the other, and there are sudden stops, starts and twists, with a maximum stress and strain on the pelvis

In the latter condition the pelvis is apt to show more rigidity, and there is a generally increased muscular development, which is better adapted to sudden spasmodic effort In the former case, there is a maximum muscular development with a minimum rigidity of the pelvis, and the musculature is more trained to continuous muscular exertion, which more readily meets the demands of labor

I have been endeavoring to obtain data confirming or disproving the foregoing theory, and should like to hear from others interested in the subject I have prepared for circulation a questionnaire and case-record blank, copies of which I shall be glad to furnish on request The questionnaire covers the following points

1 Is labor more difficult in the athletic girl, and if so, why?
2 *If strenuous athletics are detrimental, what form of* exercise would you advise?
3 At what period in a girl's life is the most injury done?

The history and record blank is a tabulated form to obtain

1 Paternal and maternal histories as to physical characteristics
2. Type, duration, etc., of the forms of athletics engaged in
3 Character of the pelvis, of labor, etc
4 Size, health, etc., of child

5615 Girard Avenue, Philadelphia

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request

CU CO BA TARRANT

To the Editor —What is there to all this?
W E Delaney M D Williamsport Pa

Answer.—"This" is a circular letter in which it is asserted that

'More favorable results are reported from the administration of CU-CO-BA, Tarrant in cases of pyelitis, inflammation of the bladder, urethritis, urethro-blenorrhea, vaginitis, leucorrhea than from any other combination"

Cu-co-ba, Tarrant (Tarrant Company, New York) is described as 'a preparation of the purest and most highly esteemed variety of balsam copaiba with a concentrated extract of cubebs" It appears to be one of the balsamic preparations for internal use that formerly were in vogue as a routine measure in the treatment of gonorrhea Little reliance is now placed in this form of treatment by the medical profession, but a portion of the public still has faith in it.

LITERATURE ON WAR SURGERY

To the Editor —Please give me information or send me literature on war surgery
Robert W Shipp M D Austin Texas

Answer.—The following is a list of references to articles which have been published in The Journal on this subject. The index of the current literature for the past year and a half contains numerous references under the headings of war, wounded soldiers, etc.

Mills L. Projectile Wounds of the Head Experiences During Recent Service in Austria The Journal Oct 23 1915, p 1424
Wounds and Hydrogen Peroxid editorial The Journal Sept. 4, 1915 p 878
Sir Wiliam Osler on Wounds and Diseases in War The Journal Aug 7 1915, p 543

HYDROCHLORIC ACID IN GASTRIC JUICE—NICHROME WIRE AS A SUBSTITUTE FOR PLATINUM

To the Editor —1 Kindly inform me what are considered the normal free hydrochloric acid findings in gastric juice I was taught and have always considered from 25 to 30 tenth normal sodium hydroxid to be about correct Niles places it at 0 2 per cent. hydrochloric acid, but also states it as being from 15 to 25 tenth normal sodium hydroxid, which is not quite 0 1 per cent. Webster says from 0 2 to 0 3 per cent hydrochloric acid, and gives his figures as from 50 to 55 or from 0 18 to 0 2 per cent hydrochloric acid Lately articles in The Journal place it as high as 0 5 per cent Will you kindly clear this muddle for me?

2 Please supply me with the name of the wire which is used in place of platinum S Roy Mills M D, Braddock, Pa

Answer —1 It is fairly safe to assert that the average of free hydrochloric acid in normal pure gastric juice is higher than it was formerly stated to be Recent examinations of pure human gastric juice by Carlson show that the total hydrochloric acid averages 0 45 per cent and the free hydrochloric acid 0 4 per cent These figures apply to gastric juice obtained from one person, but data furnished from other sources indicate that they approximate the usual averages for pure gastric juice.

2 Nichrome wire

MEDICAL HISTORY

To the Editor —1 Do any of the medical colleges in the United States have chairs of medical history?

2 Please give me a list of the best books on the history of medicine

3 Please refer me to magazines dealing with medical history or publications which have a department of medical history I L. M

Answer —1 No Fourteen schools offer courses of from three to thirty hours, and these are usually optional

2 Such a list appeared in The Journal, Feb 7, 1914

3 Publications

Janus Archives internationales pour l'histoire de la médecine et pour la géographie médicale published in Amsterdam Bimonthly
Mitteilungen zur Geschichte der Medizin und der Naturwissenschaften Hamburg
Proceedings of the Royal Society of Medicine published by Longmans Green & Co, New York Section on History of Medicine.

ORTHOFORM NEW UNDER THE HARRISON LAW

To the Editor —Please tell me whether the sale of orthoform comes under the Harrison law The local druggist has been instructed by the manufacturers that the status of orthoform is undecided
J S White M D St. Paul

Answer —As orthoform is no longer on the market, we take it that our correspondent's inquiry refers to "orthoform-new" As stated in The Journal, Nov 20, 1915, p 1837, "Treasury Decision 2194 requires the registration of any 'artificial substance or preparation which is or may be substituted for cocain, alpha or beta eucaine, or any of their salts as ordinarily prescribed or used '" New and Nonofficial Remedies, 1915, p 35, states that "orthoform-new is a local anesthetic resembling cocaine in its local action It would seem that the treasury decision contemplates registration of orthoform-new

ARTICLES ON INTESTINAL CAUSES OF EPILEPSY

To the Editor —Where can I find recent literature on the intestinal causes of epilepsy? Austin M Grove M.D, York Pa

Answer.—The following is a list of articles on this subject

Cornwall E E. Clinical Study of Case of Epilepsy Apparently of Intestinal Origin *Arch Diagnosis* July 1915 abstr, The Journal Oct. 16, 1915, p 1404
Francaviglia M C Reflex Epilepsy from Intestinal Helminthiasis *Policlinico* Rome, Aug 1, 1915 abstr The Journal Sept 4, 1915 p 913
McCoy W K. Intestinal Intoxication Headaches and Epilepsy, *Lancet Clinic* April 24 1915
Reed C A L. Probable Cause and Logical Treatment of Epilepsy, The Journal March 27 1915, p 1047
Powers H Role of Gastric and Intestinal Stasis in Some Cases of Epilepsy *Boston Med and Surg Jour* Aug 7 1913 abstr, The Journal Sept. 6 1913, p 807
Berger, F Epileptic Seizures from Appendicitis, *Med Klin* Feb 18 1912

Dr Channing W Barrett in the Chair

The Induction of Labor at Term

Dr Charles B Reed Can we determine whether or not the child has reached maturity thus fixing the time at which labor should occur? A child weighing more than 8 pounds is past maturity in 70 per cent of cases We accept seventeen weeks from conception as the day of quickening and forty-two weeks as the culmination of pregnancy Sometimes a week more is allowed, depending on the number of labors which the patient has had The work may be done under any aseptic environment, but the hospital is preferable Attention should be given to the bowels the night before, and in the morning the usual obstetric preparation of the genitalia should be made Under the strictest asepsis a Voorhees bag is introduced without rupture of the membranes, the patient being in the exaggerated lithotomy position Anesthesia is necessary only occasionally, even in primiparas If the os is not sufficiently patulous to admit the bag, it should be dilated. The bag is rolled up to a compact mass seized with a Pean forceps and passed into the uterus and filled with an ordinary hand syringe. If the pains do not start in an hour a weight of a pound or two is attached to the bag and hung over the foot of the bed Usually in from one to two hours the labor begins The bag remains for a variable period, rarely more than four hours, when it is expelled with strong pains Dilatation is practically complete The head follows the bag down, the membranes rupture and the second stage begins. From now on the case is managed according to general obstetric principles If the pains are weak and shallow, pituitary extract is given, if strong and regular, morphin and scopolamin, gas or chloroform may be used The first stage has been shortened and controlled The bag acts as a dynamic stimulant to the contractions as well as a mechanical aid to dilatation, and preserves the membranes from rupture until physiologic rupture occurs

It is believed that shortening the labor process and the preservation of maternal vitality make for immunity and prevent the infection that might follow a prolonged labor The second danger is the possibility of prematurity This happened once The case was not supervised, and an intern, supposed to be reliable, measured the uterus instead of the fetus The result was a seven months' child It has been urged as an objection to the bag that it frequently changes the location of the presenting part This occurred two or three times, but was not unfavorable.

In a series of 100 cases the results were as follows primiparas, 35, multiparas, 65, average duration of labor, seven and three-quarters hours, shortest labor fifty-five minutes, longest, thirty hours in a primipara with a hard, cartilaginous cervix, and twenty-eight hours in a multipara with cicatricial tissue in the cervix. The bag broke six times and was reinserted three times, the average time for expulsion of the bag was three hours and twenty minutes, membranes ruptured by bag, eleven, maternal deaths, two, one from placenta praevia and one from pneumonia eight days after labor, average weight of children 7 pounds, 7 ounces, smallest, 5 pounds, heaviest, 10 pounds, 5 ounces, seven babies died one a child of a primipara after a spontaneous labor of sixteen and a half hours, a baby born in asphyxia pallida, and revived with difficulty, died eight hours later, second, of a multipara, labor eleven and a half hours, blue baby, revived, and died suddenly thirty-six hours later, third and fourth children, compression of cord at outlet, one syphilitic, fifth and sixth children, moderately contracted pelvis in a primipara, one occipital posterior position stillborn This is the only case attributable to the method

Complications Version and expression, 3, breech, 4, placenta praevia 2, and collapse of the arm, 1, moderately contracted pelvis, external conjugate 8 cm, 6, stenosis, 1, motor insufficiency, 1, lacerations, 17, grave albuminuria, 1, forceps, axis traction, 2, low forceps for occipital posterior, 9, deep transverse arrest, 8, insufficiency of power, 4, total, 23 Elevation of temperature, 7

DISCUSSION

Dr J Clarence Webster The induction of labor at a calculated date is not new I should like to emphasize that there is no means of calculating the exact age of the fetus in utero, because no one yet knows when conception begins There is always a period of uncertainty of one or two or three weeks, consequently the determination of the time of maturity is guesswork to a considerable extent even in the hands of the expert A 4½ or 5 pound child may be just as well developed as one weighing 7 or 8 pounds and the measurements will be different One good object that can be gained by this procedure is the prevention of an extension beyond term, which is so bad for many mothers and children I employed a similar technic for many years, but in later years I have abandoned forceps and have used the fingers In primiparas I always dilate the vagina with the cone-shaped hand covered with a rubber glove, and I then study the condition of the cervix In the great majority of primiparas or multiparas one can dilate the cervix with the finger I have seen a very bad tear caused by the use of the vulsella on the cervix in this process, and I rarely use them Cases with rigid cervix I do not consider fit for the bag at all I think one of Dr Reed's long labors was a typical case of rigid cervix. That is a case for a vaginal or abdominal cesarean section, but not for dilatation In reference to the shortness of the labor, for sixteen years I have generally introduced the bag in the forenoon In the great majority of cases the labors have not come off until late in the evening, toward midnight, or the next morning I think a very small percentage of labors have come off within six hours In the great majority of these cases no weight was attached to the bag The attachment of a weight has advantages, if one wishes to insure the stimulation of the uterus and the early development of good pains One point that Dr Reed did not mention is that in those cases of first stage slight pains that keep the woman in uncertainty and misery and spoil sleep for a long number of hours, the introduction of a Voorhees bag is one of the very best clinical measures that can be adopted to shorten this period and bring about dilatation.

Dr. Charles E. Paddock If Dr Reed intends this as an instruction to us to deliver every case at term or as near term as we can judge the case, then we are meddling somewhat with obstetric practice In the attempt to carry out this line of treatment we will have many failures I cannot find the cervix dilated or dilated sufficiently in every primipara to admit a bag in the manner described I cannot do it without at first dilating at least one third of the primiparas that come to me, and without putting the majority of them under an anesthetic to do it In about nine tenths of the cases in which I have seen the woman throughout pregnancy I know when she is at term and I advise that she go to the hospital and have the pregnancy interrupted, provided the cervix is in such shape that it can be done without any great traumatism to the mother or danger to the child But to send out such a teaching to the world as the treatment to pursue I do not believe is right

Dr. Rudolph W Holmes I have been hearing rumors of Dr Reed s method, and I have been very skeptical about it I could not believe it possible that any one would want to induce labor in every case. People may consent to the procedure, and if there is failure there will be intense criticism, deep prejudice will be aroused, and great hardship will be worked to physicians I think it is ill advised to make it a leading practice in obstetrics I am convinced that a woman postmature is as rare as flies on the north pole Dr Reed has made the mistake of delivering a seven months' baby, and I know of a cesarean section that was done here at seven months I have used the bag in 100 cases In one case of placenta praevia I had the placenta out and the uterus tamponed in ten minutes In another case I had the bag in five days and then had to secure delivery by cutting Each bag would work for a time and then the cervix would go back. The bag does not secure sufficient dilatation—only a little more than half To put in a large bag is a great volume to put into the uterus, and it will dislodge the head When the bag comes out, the head, if favorably placed, will slip back into place. But they are dislodged, and the fact that Dr Reed had several occipitoposterior positions is suggestive. If he follows up his experience, I believe he is going to be convinced that the bag dislodges the head, and when it slips back into the pelvis it will take an abnormal position

Dr. Rachel Yarros We have been trained to leave our obstetric patients alone, or to meddle with them as little as possible In abnormal cases the bag does not work so remarkably as in Dr Reed's cases I have never had a case in a primipara in which the bag worked as successfully, and especially a small bag It is expelled before there is time for the membranes to rupture or for the baby to be delivered

Dr. N S Heaney Any method of shortening the first stage of labor without danger to the mother or child is desirable We have not used traction in connection with the bag according to the method of Dr Reed, except in placenta praevia, and then just enough weight to stop the hemorrhage Lately I have been using traction in a larger percentage of cases by means of rubber tubing from a fountain syringe

Dr. Frank Carey I am inclined to let my patients get into labor before I undertake to do anything I have not been able to tell when a patient is at full term, and until I can do that I shall hardly be inclined to resort to artificial means until the patient is in labor

Dr. R T Gillmore I have watched Dr Reed for some time, and I confess that it has taught me to fear the bringing on of labor less than before I was familiar with it I am inclined to believe Dr Reed's theory of the patient not being tired out and not having the exhaustion of the nervous elements is an important factor both in the patient's recovery and in the prevention of sepsis I am going to try it oftener in hospital cases, in which asepsis is perfect and I have better control

Dr. Carey Culbertson For some months I have used the method in my private cases, pathologic and clinical, at what we call "term" I think all obstetricians will agree that it does not make very much difference, as far as recovery goes, whether a baby is born at 280, 285 or 290 days, or throughout a fourteen-day period I have been inducing labor after the 280th day, choosing the day when the patient expressed the desire to have the baby The first stage has been shortened and the entire labor is confined to forty-eight hours, whether the patient is a primipara or a multipara The second stage is not materially altered, because the bag is out. As far as the displacement of the head is concerned, in multiparas that is not an important factor, because in the average multipara the head is not in the pelvis I find as a rule that the head returns to the pelvis when the bag is out of the cervix in the vagina There are occasional cases in which labor is not induced, in which it cannot be induced by any artificial means and the patient must be delivered surgically, but that does not happen oftener than once in twelve or fifteen times I think we are using a larger bag than Dr Reed I have never found it necessary to put the bag in three or four or five times I should not do it, especially every day I should allow two or three days to intervene As a rule, I do not find it necessary to employ traction, but when I do I use the elastic tube. It is important not to make too much traction, and the bag can be too tight in the cervix. A little tension is all that is required I usually expect contractions to occur immediately after the introduction of the bag When the bag has been in all night or all day and pains do not come on, I think it best to take the bag out It certainly should not be left in twenty-four hours

Dr Mark T Goldstine The impression is that the technic of this is simple I have just the opposite impression I do not think the introduction of the bag and the management of the case afterward is always as simple as one would be inclined to believe from what has been said here I would not say that the introduction of the bag is difficult, but the asepsis and carefulness required after the bag is introduced are far from simple, and it requires either the man himself to watch his patient or some one who has had a great deal of experience Dr Reed's success I attribute as much to the lack of intravaginal manipulation as to the short labor In the great majority of cases the only intravaginal manipulation done would be the introduction of the bag No other vaginal examinations are made I think that has some bearing on his lack of morbidity The work will impress a great many men I should like to see the same procedure tried in a series of normal cases, leaving out the abnormal ones

Dr Charles B Reed It makes little difference whether the child comes two weeks before full term or not, it does make a difference whether the child is delivered two weeks after the expected time Dr Paddock made use of the term "meddlesome obstetrics" I suppose it is I used to hear the term applied to surgery when some one was going to open an appendiceal abscess The point is, Are we going to control the situation from the beginning, or shirk responsibility? If we are going to be men we will take the responsibility and take what blame comes to us and not claim to be obstetricians As to the introductoin of the bag, Dr Paddock and others manifested an unwillingness to do it without an anesthetic My associates at the hospital see one bag introduced, and after that they introduce it themselves My interns will put in the bag without an anesthetic and without any difficulty whatever, provided they have the manual dexterity Deliver at the time set, in as short a time as possible, and make it as nearly painless as possible The small bag has been chosen purposely We have experimented with large sized bags We have selected the small bag deliberately because we do not want to get complete dilatation We inaugurate labor and let Nature complete it Formerly when the bag came out the pains might cease, but now we have pituitary extract, the labor continues and the woman is delivered The babies do not suffer and the women do not suffer more than a few hours The technic is important, and I am free to say that the cases do require an unusual amount of attention.

1 **Complement Fixation in Tuberculosis**—Craig believes that in this method we possess a valuable aid in the diagnosis of active tuberculous infection and a guide as to the results of therapeutic measures The general technic of the complement fixation test for tuberculosis experimented with is that employed in making the Wassermann test. The

antigen employed consists of an extract of several strains of the human tubercle bacillus A human hemolytic system was employed As complement guinea-pig blood serum was used, Craig tested the blood of 166 patients suffering from pulmonary tuberculosis In addition, the blood of 150 syphilitic as well as of 100 patients suffering from other diseases was tested, and also 150 normal individuals who were used as controls Of the 142 cases of pulmonary tuberculosis that reacted to the test, 119 gave a double-plus reaction and 23 a plus reaction, of the 103 cases of active infection reacting, 87 gave a double-plus reaction and 16 a plus reaction, while of the 39 inactive cases of infection, 32 gave a double-plus reaction and 7 a plus reaction Of 150 syphilitics tested, all giving a positive Wassermann, not one gave a positive reaction with the antigen employed in the complement fixation test for tuberculosis Of the patients suffering from other diseases, 100 in number, all gave a negative reaction The blood serum of 150 individuals in good health and free from tuberculous infection was tested and a negative result was obtained in every instance The results of the test also demonstrate that while a patient may have a clinically inactive tuberculous infection, the blood often gives a positive complement fixation reaction, and this fact, Craig says, should prove of considerable value in the control of the treatment of the disease

2 Abstracted in The Journal, June 12, p 2013

7 **Heart Cases Showing Vagus Influence**—One of the cases cited by Sicard and Meara, a case of simple increased frequency of the heart's action, was controlled and slowed by compression of the right vagus governing the sinus node, the slowed impulses from which were transmitted through junctional tissue to the ventricles, maintaining normal rhythm, this is what one would expect The other case, one of tachycardia of auricular origin, was slowed by compression of the left vagus

9 **Tubercle Bacilli Not Stainable by Ziehl.**—In any patient suspected of tuberculosis in whom Ziehl forms cannot be demonstrated, Meader says, it is as important to search for Gram-staining forms as it was for the Ziehl-staining bacilli, and a diagnosis of tuberculosis cannot be certainly excluded until such search has proved negative The type of case in which they are characteristically present strongly supports the conception that they represent a resistance stage of low virulence, and their presence alone warrants a much more favorable prognosis than does the presence of Ziehl forms. Further, they are probably a definite factor of as yet undetermined importance in the spread of tuberculosis

10 **Hodgkin's Disease**—According to Cunningham, the treatment of Hodgkin's disease is excision of all foci of infection and Roentgen rays Vaccines are of no value For diagnosis in lymphatic disturbances, more than one gland should be obtained The following evidence is given to support it as an infection, bacterial or protozoan in origin (a) the histology is that of an inflammatory reaction, (b) injections of gland emulsions have caused temporary lymphatic enlargement in lower animals (literature), (c) the fever resembles closely that of other infections, (d) the leukocytosis, (e) the exudate when serous surfaces are involved. The specific organism has not been isolated

American Journal of Physiology, Baltimore

18 *Evidence of Vasotonic and Vasoreflex Mechanism. W T Porter and A. H. Turner Boston.

12 **Effect of Chloroform on Factors of Coagulation**—In his experimental work Minot found that antithrombin is rendered inactive by chloroform and ether, thus allowing free thrombin if present in an oxalated plasma to clot fibrinogen Prothrombin is not converted to thrombin by chloroform Chloroform can precipitate both fibrinogen and prothrombin from an oxalated plasm Chloroform does not weaken the action of a solution of pure thrombin Ether does slightly Antithrombin could not be recovered from chloroform or ether extracts of serum or plasma, unheated or heated to 60 C, and is not exactly identical to antitrypsin or to Doyon's antithrombin In one chloroform poisoned rabbit the antithrombin of the blood was decreased below normal

14 **Cardio-Inhibitory Center**—The results of the experiments made by Miller and Bowman show that the cardio-inhibitory center is situated in the dorsal vagus nucleus and are thus in harmony with the histologic investigations of Kohnstamm and of van Gehuchten and Molhant

18 **Vasotonic and Vasoreflex Mechanism.**—The method employed by Porter and Turner consisted in applying curare to the vasomotor center hitherto believed to control both the vasotonic and the vasoreflex function Curare left the tonus unchanged, while the depressor and the sciatic vasomotor reflexes were more than doubled Curare thus separated the vasoreflex from the vasotonic function Certain doses of alcohol leave the tonus unchanged while completely suspending the vasomotor reflexes Neither phenomenon would be possible if the vasotonic and the vasoreflex mechanism were identical

2 Photographic Action of Radio-Active Sources. W Makower

3 Fluorescent Screen Localization by Parallax Method A C Jordan
4 *Roentgenograms to Illustrate Velocity of Rifle Bullet as Determining Factor in Extent of Injury G Vilvandre.

1 **New Therapeutic Roentgen Ray Localizer**—The principle employed by Knox and Caulfeild is that of the rotating tube, making a circle on the surface and focusing the sheaf of rays on a point in the interior whose depth is determined by the angle at which the tube box is fixed The chief field of action for the centering device is in the treatment of malignant disease It will be possible to attack a growth from all aspects and the maximum dose to be administered at will to selected areas of the growth

4 **Roentgenograms to Illustrate Velocity of Rifle Bullet**—The series of cases reported by Vilvandre illustrates the point that the damage done by rifle bullets is dependent on the velocity of the missile rather than on the texture of the bone

11 *Notes on Certain Insecticides A Castellani and T W Jackson
12 *Inoculation of Smallpox as Prophylactic Measure as Practiced by Natives at Djen in Nigeria H A Foy
13 Schistosomiasis in Natal F G Cawston
14 Case of Oriental Sore Treated by Antimonium Tartaratum (Tartar Emetic) Locally G C Low

11 **Insecticides**—In regard to solid and liquid insecticides, the substances which Castellani and Jackson have found to be deleterious to body-lice are, in the order of their efficiency Kerosene oil, petrolatum, guaiacol, anise preparations, iodoform, compound solution of cresol and similar preparations, phenol solution, naphthalene, camphor Pyrethrum has a feeble action on lice, while boric acid, sulphur, mercuric chlorid and zinc sulphate, when used in powder form, have apparently no action whatever As regards bedbugs, kerosene oil is the best insecticide Next to it comes guaiacol, one of the most active drugs of those the authors have tried

Substances which are powerful licecides may have little or no action on bedbugs, and vice versa For instance, iodoform, which kills lice within ten to fifteen minutes, has practically no deleterious action on bedbugs, which may live for more than twenty-four hours when exposed to it It has also little effect on fleas Pyrethrum, on the other hand, has a much more powerful action on bedbugs than on lice

For use against lice on a large scale, as among troops and prisoners, perhaps the best insecticide powder is naphthalene This substance has a lower licecide action than kerosene oil, guaiacol, iodoform and anise preparations, but it has a less displeasing odor than the first three named In stored blankets and clothing it is also practicable and of use,
are found on the clothing and blankets
returns to the pelvis summer Naphthalene is useful also for
vagina There are ot rent action on moths Castellani and
induced, in which it can here of insecticide powders As
and the patient must be du es, the American Red Cross Sani-
happen oftener than once in iction to kerosene by its daily use
we are using a larger bag tha For the better class of patients
it necessary to put the bag in - is to be preferred to naphtha-
should not do it, especially ever or is not displeasing, while it
three days to intervene As a ru dition to lice and fleas Such
to employ traction, but when I do immer in hot countries, as

17 *Cholera, One Hundred Cases G Delamare
18 Blue Staining Granules in the Mononuclears in Normal and in Leukemic Blood (Les granulations azurophiles des mono nucleaires) C Aubertin and H Chabanier
19 *The Cardio Peritoneal Syndromes in Typhoid Fever L Bernard and J Paraf

17 **Cholera**—Delamare's study is based on 100 cases of which he had charge in Constantinople in 1912 These patients were nearly all otherwise healthy, there was a history of malaria in only ten The general mortality during the epidemic was 47 per cent, but in his cases it was only 30 per cent His main reliance was on baths, and heat applied to the feet and hands, with saline infusion and heart tonics Yoghurt and rice were the main diet during convalescence, and there were no gastro-intestinal after-effects

19 **The Heart and Peritoneum in Typhoid Fever**—Bernard and Paraf call attention to the symptoms of weakness on the part of the heart and of irritation of the peritoneum before there is actual peritonitis With both the cardiac asthenia and the preperitonitic syndrome, we have meteorism, small, rapid pulse and cyanosis or pallor of the face or the leaden tint of peritonitis, but the heart sounds reveal the weakening of the heart action, while the muscular defense in the abdominal wall calls attention to the trouble below, thus differentiating the two syndromes When the two are associated death generally ensues, even without actual development of peritonitis or true heart collapse They describe some typical cases in which the cardiac or the peritoneal syndrome preceded the other The measures required for one are contraindicated by the other In the preperitonitic stage prompt operative treatment may be the only means to ward off the impending peritonitis In their one case of recovery they varied the treatment according to which syndrome predominated at the moment, changing from baths to ice or heart tonics as the indications varied

Archives des Maladies du Cœur, etc, Paris

November, VIII, No 11, pp 361 436

20 *Nature and Cause of Accidents from Resorption in Edema H Vaquez.
21 *Typhoid Appearing as a Hemorrhagic Syndrome J Milhit and H Chabanier

20 **Disturbances from Absorption in Edema**—Vaquez refers to the dizziness, headache, dyspnea, general weakness and other symptoms sometimes noted when edematous fluid is being absorbed, be the fluid has been thrown off by the kidneys or evacuated otherwise Swelling of the joints, cramps in the calf of the leg, somnolency, stupor or insomnia with agitation, vomiting or convulsions, may also be encoun-

tered, but they subside as a rule as soon as ample diuresis is established In one of his cases the congestion of the face was so intense that some of the capillaries seemed to have ruptured Andral and Kostkevitch have each reported negative necropsy findings in a case of fatal accidents from this cause Vaquez reviews the data on the subject and agrees with those who regard the disturbances as analogous to serum sickness As the dropsical accumulations become mobilized and are taken up into the blood they induce actual anaphylaxis The phenomena of this auto-anaphylaxis also include the dropping of the arterial blood pressure and considerable but transient albuminuria

The third criterion of the "anaphylactic shock"—leukopenia—has not been sought for systematically to date, but de Jong and Bezançon reported a leukopenia like that of anaphylactic shock in a case in which part of a pleural effusion was siphoned out, but quite a quantity still left Vaquez noted in one case a marked drop in arterial tension after diuresis amounting to 18 liters When the edema fluid is drained away through the skin, there is no chance for the conflict between the albuminoids in the fluid and the colloids in the blood, which causes the phenomena The latter are more frequent in the elderly because their kidneys are less able to cope with the task of eliminating the mobilized fluids The anaphylactic phenomena are of course most liable to occur and most pronounced during the period between the mobilization of the dropsical accumulations and the liberating diuresis Analysis of the phenomena reveals that they are essentially the same as those induced by Richet in his experimental research on anaphylaxis and those recorded by Widal in clinical paroxysmal hemoglobinuria

21 Hemorrhagic Onset of Typhoid—The patient was a young man who complained of headache and pain in the lumbar region and the next day he voided red urine This suggested scarlet fever and he was sent to the isolation hospital, but the absence of sore throat and eruption, and a history of scarlet fever in childhood finally excluded this disease. The intestines liver and lungs seemed to be normal but the agglutination test finally pointed to typhoid Hemorrhagic vesicles developed on the body with epistaxis, and spitting of blood, till death the twenty-fourth day

34 Inhibiting Action of Malachite Green and Kristallviolett on Experimental Septicemia in Guinea Pigs (Wirkung einiger Anilinfarbstoffe auf experimentell erzeugte Septikamie bei Tieren) G Hofer

27 Surgical Aspects of Typhoid Complications—Riedel analyzes here his experiences with forty operative typhoid cases mostly tardy complications He remarks that the number of such complications is probably larger than has been suspected hitherto, as the connection with typhoid years before has often been overlooked Complications in soft parts are particularly dangerous, especially peritonitis from diapedesis Typhoid appendicitis is controlled comparatively easily, and typhoid cholecystitis still more readily Bone tissue is vitally less important than soft part tissues, and has unlimited capacity for regeneration Hence typhoid foci in bones are not much to be feared unless they are located at particularly unfavorable points Typhoid foci in joints heal favorably if operated on at the proper time One boy of 14 seven months after appendicectomy, suddenly developed symptoms of peritonitis ascribed to the stump of the appendix Laparotomy the third day confirmed the diffuse peritonitis, but no cause for it could be detected until necropsy next day revealed flat typhoid ulcers in the intestines, the serosa above absolutely intact This case suggests that a symptomless typhoid may be responsible for many cases of so-called spontaneous peritonitis In one case he mistook ordinary swollen glands back of the apparently sound appendix for typhoid appendicitis, and Thomas and Frazier have reported eight cases of typhoid suppuration in mesenteric glands

Another patient was a man of 35 with multiple posttyphoid fistulas near the anus beyond operative repair One woman with senile paranoia at 57 had peritonitis from diapedesis and typhoid was assumed The intestines were found sound but typhoid bacilli were cultivated from the gallbladder One patient with purulent typhoid thrombophlebitis of the internal saphenous vein was saved by its extirpation Thrombosis followed in the external saphenous vein but no suppuration In another case thrombosis in the femoral vein in the course of typhoid was followed four years later by thrombophlebitis in the external saphenous and the fever persisted for weeks after extirpation of the vein

The costal cartilages were the seat of the skeletal typhoid process in eleven of twenty-three cases, and the tibia in six The process healed smoothly, as a rule, after resection The most serious were typhoid foci in the costal arch He had five such cases, and remarks that one can be extravagant in resecting under these conditions as repair proceeds promptly and thoroughly when there is no infection In infected cases the operation has to be frightfully radical, and the perichondrium grows only bone, not cartilage In his joint cases, the interval since the typhoid was twelve years in the case of a man of 44 who had had an osteomyelitic process in the hip joint for a year It healed after resection Puncture of the hip joint in another case, in a boy of 16, brought typhoid bacilli, and recovery was soon complete under drainage alone In two other cases the knee or hip joint developed deforming arthritis after the typhoid joint trouble

28 Dissolved Albumin in Stomach Content as Sign of Cancer—Zoeppritz points out that the presence of dissolved albumin in the fasting stomach does not decide between ulcerative and nonulcerative processes, but the absence of albumin renders the assumption of malignant disease highly improbable Stagnation of stomach contents and lack of the normal acid favor the appearance of albumin in the stomach washings but do not influence its production Albumin may sometimes be found in the clinically normal stomach, but it occurs more frequently with chronic gastric trouble His tabulated records of forty-eight operative cases of gastric cancer showed a positive response to the Esbach test in all but 8 cases, and there was no free acid in 7 in this group and very little in the remaining case His tables show further a positive reaction in 14 of 21 operative cases of gastric ulcer and in 5 of 6 without an operation, also in 5 of 6 operative cases of chronic gastritis and in 8 of 8 nonoperative cases, in 4 of 7 other operative stomach affections and in 5 of 5 nonoperative, in 14 of 16 operative abdominal affections and in 12 of 12 in which no operation was attempted In one case an extensive cancer in the submucosa had irritated the mucosa and caused secretion of mucin and nuclein, which gave the positive albumin reaction, although there was scarcely any ulceration and this was close to the gaping pylorus The various groups are tabulated in detail and the reaction compared to other tests for cancer In 135 cases of gastric cancer at Kiel occult or visible blood was found in 95 per cent, there was emaciation in 90 per cent, anacidity in 89, dissolved albumin in 83, lactic acid in 67, long bacilli in 64 and a palpable tumor also in 64 per cent The albumin reaction was positive, if at all, very soon after the first symptoms appeared The test for albumin is simple and easy if the stomach motor function is normal, but with impaired evacuation it is a tedious matter to rinse the stomach clean, and the slightest erosion of the stomach walls nullifies the findings of the test

33 **Transient Glucosuria with Fractures**—Konjetzny and Weiland report from the surgical clinic at Kiel 34 cases of fracture in which there were no traces of traumatic glucosuria, 3 in which the examination on account of the accident revealed hitherto unsuspected diabetes, and 24 of alimentary glucosuria after fracture of the leg or arm The sugar content of the blood was recorded in 36 cases and found abnormally high in 31 Of the total 83 fracture cases there was no tendency to glucosuria in 48 1 per cent, while in 40 9 per cent there was actual traumatic glucosuria, and in 7 2 per cent alimentary glucosuria The traumatic glucosuria is transient and there is no polyuria or polydipsia, but it is accompanied by hyperglycemia They regard it as a transient central lesion, like the sugar puncture, it may be in the nature of fat embolism

37 *Hemoglobinuria from Beans (Il favismo) A. Gasbarrini
38 Workmen's Compensation and Safety Appliances. (La profilassi degli infortuni e gli interessi degli operai) G Dragotti
39 Subcutaneous Nodules in Acute Articular Rheumatism P Ercolani

37 **Hemolytic Jaundice from Beans**—Favism, from *fava*, "bean," is the name given in Italy to an acute febrile anemia with jaundice and hemoglobinuria which is not uncommon there, and is ascribed to the eating of fresh, raw or dried and cooked beans or smelling the blossoms of bean plants Gasbarrini accepts it as a morbid entity, the result of acute toxic hemolysis It was mentioned by Herodotus and by numerous Italian writers in the last century, but Fermi (1905) was the first to apply experimental research in the study of favism His conclusions favored the assumption of acute toxic action of beans in the predisposed In the very young it is liable to prove rapidly fatal It is known only where beans are cultivated on an extensive scale, occurs usually in the spring, and Fermi noticed a hereditary character in 20 per cent of his cases, sometimes through several generations The inherited predisposition may not become manifest till adult life Infants and the elderly generally escape Quinin has been excluded as a factor by six Italian physicians who have made a special study of this question The Wassermann reaction has always been found negative in favism, and the history of the frequent cases also excludes syphilis as a factor Fermi has reported that in 1,211 cases in Sardinia, 752 were ascribed to ingestion of beans and the others to inhalation of the odor or pollen Tomaselli has reported cases in which the disturbances occurred immediately after passing through a field of beans in flower Montano had one patient affected anew whenever he inhaled the odor of bean blossoms or passed near a pile of fresh beans Nurslings can also be affected when the predisposed mother eats beans The affection does not seem to be contagious and there is no period of incubation, the disturbances coming on at latest in a day or so after ingestion of the beans or in from two to six hours after inhalation Acute fever, black urine, intense anemia and jaundice distinguish favism and there may be a rigor, vomiting and diarrhea No one has been able to isolate from beans any toxic substance that might be responsible for this toxic hemolysis, some believe that a fungus on the beans is responsible for the symptoms Others accept a bacterial origin, but no evidence has been presented to sustain this assumption There does not seem to be any idiosyncrasy to quinin in persons affected with or predisposed to favism With paroxysmal hemoglobinuria there is not the extreme prostration characteristic of favism, but there is a close resemblance between the latter and Plehn's hemoglobinuric icterus in all its forms, from the abortive and mild to the grave, the fulminating and the hemorrhagic Even the blood picture seems to be identical Echinococcus disease of the liver is liable to be mistaken for favism or vice versa, as both are prevalent in the same regions The cadaver of one child with acute favism showed merely changes indicating some old liver and spleen trouble of obscure cause This is the only complete necropsy on record As soon as the hemoglobinuria is past, recovery proceeds rapidly Some of the predisposed suffer whenever they are exposed to the assumed cause, in others, one attack seems to confer immunity for years or permanently In Fermi's statistics the mortality was 8 per cent It is highest in children and the disease seems to be especially grave in certain seasons Treatment can be only symptomatic Injections of horse serum and of cholesterin and calcium chlorid by the mouth have been tried but without decisive results

Hygiea, Stockholm

LXXVII, No 20, pp 1185 1264

40 *Abuse of Tobacco from the Medical Standpoint (Om tobaksmissbruket från medicinsk synpunkt) C F Höckert

40 **Abuse of Tobacco from the Medical Standpoint.**—This issue of *Hygiea* has an unusually good portrait of Ehrlich, with a ten-page tribute to his work The usual comment on the picture, however, is that Ehrlich is shown without his inevitable cigar, and it is a curious coincidence that the rest of the number is devoted to the "Abuse of Tobacco" Its use and abuse are discussed from the historical and geographical as well as the medical standpoint Some recent chemical and experimental research is described and some of the new books on the subject are reviewed They include Bresler's "Tabakologia medicinalis" (1911) and von Frankl-Hochwart's "Nervous Affections of Tobacco Smokers" (1912)

Ugeskrift for Læger, Copenhagen

November 11, LXXVII, No 45, pp 1737 1784

41 *Pronounced Lesions in Untreated Syphilis with Negative Wassermann Reaction A L Følnss

41 **Manifest Syphilis, Untreated, with Negative Wassermann Reaction**—Følnss has encountered 243 cases of syphilis in which there had been no attempt at treatment In 172 the lesions were those of the secondary stage of the disease and in 20 of the tertiary stage Of these two groups with manifest syphilitic lesions, there was no reaction to the Wassermann test in 10 of the 172 secondary cases nor in 4 of the 20 extensive tertiary cases nor in 11 of the 51 cases with tertiary lesions restricted to a single small area The negative response may veer to positive or vice versa within a few days, so that repetition of the test in dubious cases is advisable after the reactivation liable when treatment is instituted Følnss remarks that a positive reaction is extremely important with latent syphilis and also in dubious cases, although, he reiterates, we must not forget that it is never an "organ diagnosis" A repeatedly negative reaction, he adds, is not particularly important for the diagnosis, especially when the patient has been taking recent treatment His experience shows further that even with untreated syphilis a negative reaction is not uncommon, nearly 10 per cent in his cases (25 in 243) These negative cases are described in detail and compared with those published by others

JOURNALS INDEXED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT JULY-DECEMBER, 1915

The following journals have been indexed in the Current Literature Department of The Journal during the past six months Any of the foreign journals, except those starred, will be lent by The Journal to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days Only one journal may be borrowed at a time Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed This covers the average expense of mailing a journal Domestic journals can be obtained by sending the approximate amount direct to the respective publishers Thus most of the journals indexed are accessible to the general practitioner, no matter where he may be located.

EXPLANATION OF THE USE OF THE INDEX

This is an index not only to the reading matter in THE JOURNAL, but also to original articles in the principal medical periodicals of this and other countries The reading matter appearing in THE JOURNAL is distinguished by the use of black-faced numerals

The letters used to explain in which department the matter indexed appears are as follows "E," Editorial, "C," Correspondence, "T," Therapeutics, "Ml," Medicolegal, "P," Propaganda for Reform, "ME," Medical Economics, "ab," abstract, the star (*) indicates an "Original Article" in THE JOURNAL

This is a subject index and one should, therefore, look for the chief word, with the following exceptions Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B" "D" and S" Matter pertaining to the Association is indexed under American Medical Association"

All matter is indexed under the most important word of the heading used in THE JOURNAL, and also under the subject heading For instance, abscess of the brain will be found under 'abscess," as well as under 'brain" Such titles as "ocular manifestations, etc.," have been indexed under 'Eye" Cross references have been liberally used

The figures in parentheses refer to the paragraph, the number following to the page in THE JOURNAL

ABORTION cause and treatment,
***1262**

This reference is to an original article in THE JOURNAL, as shown both by the star and by the black-faced numerals indicating the page

ACID uric, in blood Manze Zondek test for **1748**

This reference as indicated by the black-faced figures, is also in THE JOURNAL, and on turning to page 1748 we find an answer to a question in the Department of Queries and Minor Notes

ABDOMEN, anomalies of (149) **1143**

In this reference, the (149) indicates that the article is in the Current Literature Department and the fact that the page number is in black-faced type shows that the article is abstracted and discussed in THE JOURNAL Turning to page 1143, we find (149) refers to an article by F G DuBose in the *Southern Medical Journal*, September

ACETONE bodies in urine, significa-
tion of (24) 831

The fact that in this last reference the page is given in ordinary type indicates that only the title of the article is given Turning to page 831 we find that the numeral (24) refers to a paper on that subject by B Derham which appeared in the *Lancet*, July 31

In the AUTHOR S INDEX are the names of the authors of articles which have appeared in THE JOURNAL of the American Medical Association and of articles that have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals The black-faced numerals indicate that the article is in THE JOURNAL, either in full or in abstract The star (*) preceding the page number indicates an original article.

SUBJECT INDEX

ABDERHALDEN SERODIAGNOSIS See Serodiagnosis
ABDOMEN anomalies of (149) **1143**
  cancer mediastinum syndrome from metastasis of (74) 987
  cancer Roentgen ray and diagnosis of (105) 538
  contusion of (101) 2042
  diagnosis of diseases of (66) 904 (76) 905
  disease stomach symptoms and (74) 2123
  drainage of (108) 982
  fixation of abdominal organs significance of ***1809**
  fremitus (107) 1316
  herniæ of wall in fat women (112) 905
  incision transverse (33) 2033
  injuries (76) 1059
  intestinal grafting in repair and reconstruction of (137) 199
  intra abdominal injury from slight trauma (97) 1586
  muscles paralysis of with acute anterior poliomyelitis, (77) 1684
  pain cured by vomiting one ascaris lumbricoides (40) 59
  plastic operation on perineum and (143) 559
  Ptosis of See Splanchnoptosis
  subinfection from foci in pelvis and ***666**
  Surgery See also Laparotomies
  surgery of pelvis and (12) 1755
  tuberculosis of (65) 361
  viscera failure to recognize normal variations in cause of poor results of abdominal surgery (43) 279
  wall thickness of as index of nourishment in children (67) **1147**
  walls transparency of in pregnancy at term (61) 465 **642—C**
  wounds (99) 205 (60) 367 (64) 1147 (67) 1313, (109 113 114) 1764
  wounds closure of technic (117) 649
  wounds compression in (75) 308
  wounds gunshot penetrating and perforating (133) 829
  wounds gunshot perforating (19) 217
  wounds high fatality of and immediate operative treatment (93) 655
  wounds in war (56) 202, (144) 1068
ABDOMEN wounds nonpenetrating peritoneal symptoms from (47), 1953
  wounds operative treatment of in war (61) 910 (76) 911 (74) 1591 (20) 2202
  wounds routine operations for (41) 464
  wounds treatment of (50) 1312, 1743
  wounds treatment of in ambulances at front 348 (31) 1492
ABNORMALITIES inheritance of **1916—E**
ABORTION cause and treatment ***1262**
  criminal and professional secrecy **634**
  febrile treatment of (50) 1223
  habitual and Wassermann reaction (112) 566
  incomplete medical treatment of **1398—ab**
  infective in guinea pigs (8) 1490
  intestinal hemorrhage and perforation of ileum complicating typhoid (128) 906
  perforation of uterus in causes prevention and treatment (49) 1223
  pituitary extract in inevitable and incomplete (69) 1679
  reactions epidemic in children, studies on (5) 1138
  septic treatment of puerperal infection and **1482—ab**
ABSCESS See also Cellulitis Phlegmon
ABSCESS blind dental and systemic disease **456—ab *1619**
  brain (63) 2120
  brain multiple (49) 361
  brain multiple tuberculous and dementia (110) 1758
  breast during lactation incision of (34) 1057
  camphor (90) 205
  cerebrum due to suppurative tonsillitis (77) 1757
  fistulas pyuria and bacilluria as complications following nephrectomy for tuberculosis (130) 1765
  fixation and immunization (101) 467
  Friedmann's tuberculosis vaccine injection followed by local, (106) 1686
  kerion complicated by (122) 2037
  liver, (19) 2261
  liver etiology of doubtful (111) 198
ABSCESS lung and bronchiectasis surgery of (118) 2198
  lung medical aspects of empyema and (14) 2198
  mastoid blood clot dressing in closing wound in operation for **1578—ab**
  mastoid idiopathic ***501**
  meningitic suppurative extradural of posterior fossa of skull after purulent tonsillitis (38) 53
  on optic nerve (20) 902
  parapharyngeal distinguished from retropharyngeal and peritonsillar (9) 646
  perinephritic (91) 362 (131) 1853
  peritonsillar death from hemorrhage following (43) 1307
  spleen in woman of thirty-eight (66) 1063
  spleen report of case (35) 902
  subdiaphragmatic (57) 2122
  subpectoral staphylococcus septicemia complicated by (113) 462
  subperiosteal of maxillary sinus (44) 1307
  subphrenic gas differential percussion finding with (57) 1501
  temporosphenoidal acute purulent otitis media complicated by mastoiditis and (161) 1143
  temporosphenoidal discovered by exploration through multiple incision in dura (152) 199
  temporosphenoidal unusual complications in (48) 361
  tongue **1135—ab**
  tropical primary malignant adenoma of liver simulating (20) 560
  tubo ovarian intestine and ureter obstruction abdominal sections for (6) 982
  umbilical vein (54) 1757
ABSTAINERS comparative mortality experience among nonabstainers and (109) 1758
ACADEMY of Medicine and campaign against alcoholism **637**
  of Medicine and war **813**
  of Sciences in war **183**
ACANTHOCEPHALIA in North American amphibia (78) 558
ACANTHOSIS NIGRICANS (101) 649 (143) 2044
  indication of internal malignancy ***925**
ACCIDENTS automobile deaths from **433—ab**
  automobile statistics regarding **1479—C 2107—C**
  benzin **35—E**
ACCIDENTS coke oven **182**
  elevator **23—ab**
  hernias from industrial and other (52) 1312
  industrial and internal medicine (27) 1584
  industrial and so called strained back (24) 1584
  industrial and traumatic neuroses prognosis and treatment (25) 1584
  industrial temporary compensation of workmen after (90) 751
  metal mine in 1914 **1830**
  neuroses following compensation of workmen for (104) 281
  railway **1265**
  railway immediate and after treatment of **2117—ab**
  surgery troublesome sequelae in (139) 829
ACCOMMODATION and cornea **1836—C**
ACETONE bodies clinical pathology of (53) 53
  bodies form of diabetic coma not due to (69) 741
  bodies in diabetes mellitus ***1715**
  curve in experimental acidosis (134) 1594
  elimination of diacetic acid and in 214 surgical cases (10) **1947**
  in urine carbohydrate starvation and (98) 1060
  in urine signification of (24) 831
  in urine test for **2108**
  test for simplification of (47) 908
ACHALASIA of cardia (31) 561
ACHONDROPLASIA (101) 912 (91) 1141
ACHYLIA and anemia with chronic polyarthritis (131) **1958**
  gastrica analysis of (6) 358
ACID acetyl salicylic incompatibility of quinin with and other organic acids **2167**
  amino and tumor tissue **1373—E**
  amino content of blood study of (39) 556
  amino content of feedingstuffs (47) 556
  amino metabolism of proteins and rate of (51) 979
  amino spectographic study of polypeptids and (78) 1757
  amino, urea formation from function of liver in (42) 556
  base equilibria in blood after parathyroidectomy (65) 2036
  boric and salicylic United States Department of Agriculture warns against use of as preservatives **888**

ACID, boric, and yellow petrolatum dressing *1279
boric, constitutionality of state food law prohibiting use of, 1842—Ml
Carbolic See Phenol
cholalic, salts, activation of pancreas lipase by, research on, (88) 62
cynurenic, (67) 1307
diacetic elimination of acetone and in 214 surgical cases, (20) 1947
electrolytes in diffusion of, into egg of fundulus (67) 2035
epimeric monocarboxylic sugar configuration and rotation of (68) 2035
excretion in nephritis, (35) 459
excretion of ammonia and after parathyroidectomy, (66) 2036
fatty, of food passage of, into breast of goat, (32) 979
formic, 1915
glucuronic in urine test of liver during pregnancy (40) 1953
hippuric and benzoic in blood and tissue, determination of, (43) 197
hippuric, synthesis of 805—E
hippuric, synthesis of in animal organism and occurrence of free benzoic acid in urine (49) 196
hippuric synthesis of in nephrectomized dogs, (44) 196
hydrochloric and charcoal in gastrogenous diarrhea (73) 2126
hydrochloric, as antiseptic in naval medical service (10) 1951
hydrochloric formation of, in stomach 625—E 2257
hypochlorous antiseptic action of in wounds, (4) 744
hypochlorous in gas gangrene (1) 1759
Intoxication See Acidosis
lactic, in incipient tuberculosis, (66) 986
lactic, vaginal douches in puerperal infection (67) 910
d-lyxohexosaminic and alpha alphalanhydromucic (62) 1307
organic incompatibility of quinin with aspirin and, 2187
oxalic, excretion in urine of childdren, (3) 2198
oxalic producing penicillium (56) 1307
oxyproteic in urine as sign of cancer, determination of (120) 206
phosphoric, in urine quantitative test for, (100) 370
picric and benzidin stain, (92) 1851
picric, as antiseptic (22) 1407
picric jaundice from absorption of, (34) 984
picric, jaundice from examination of urine of soldiers with 1831
production in liver in narcosis, 335—E
Salicylic See also Salicylates
salicylic in acute articular rheumatism, (87) 1148
salicylic in suppurative affections of skin, (75) 2126
salicylic, pure in acute articular rheumatism (100) 834
